INTRODUCTION

Construction projects are realised by carrying out various activities which are dependent on one another through network relationships, is deterministic with regard to the duration assigned to the execution of the activities and the results produced in certain values. Unfortunately, construction activities are performed under uncertain conditions. Project risks cause variations in activity duration, and in turn the entire network is affected by uncertainty. In this context, activity duration can be represented by fuzzy sets, and CPM network calculations can be performed by fuzzy operations through a method developed in this study. Since the duration of activities is represented by fuzzy sets, and network calculations can be performed by fuzzy operations, the activity early/late start/finish times and the project completion time are calculated as fuzzy sets by the proposed method. An example CPM application with fuzzy sets is also presented in the paper. The findings show that CPM is applicable with fuzzy sets, and the developed method operates well for modelling the uncertainty in CPM calculations.

Keywords: construction management, critical path method, scheduling, fuzzy sets, uncertainty

A CPM-based scheduling method for construction projects with fuzzy sets and fuzzy operations

O. Ökmen, A. Öztas
the activity durations are represented by fuzzy numbers and the network calculations are performed by fuzzy operations, the activity early/late start/finish times and the project completion time or the project duration are calculated as fuzzy numbers through this new method. In other words, the effect of uncertainty on the results of CPM is modelled. Furthermore, the evaluation of activity/path criticalness is realised by using the geometric centres of the activity early/late times.

Simulation-based, probabilistic- or fuzzy set-based methods have been used in the past by researchers to model the uncertain activity durations and the uncertainty effect on the activity networks (Ayyub & Haldar 1984; AbouRizk & Halphin 1992; Díaz & Hadipriono 1993; Wu & Hadipriono 1994). Program Evaluation and Review Technique (PERT) is the most popular probabilistic method developed for this purpose. While certain durations are assigned to the activities in CPM, activity durations are assumed as variables and represented by minimum, maximum and most likely durations in PERT. Through a simplification process, the expected durations and the variances of variable activity durations are calculated by utilising the minimum, maximum, and most likely durations. Subsequently, the traditional CPM calculations are performed by using the expected activity durations, and then the critical path is detected. The expected durations and variances of the activities on the critical path are added, and the project completion time is assumed to follow normal probability distribution having these calculated values as the distribution parameters, i.e. the mean and variance. Since the project completion time is obtained as a normal probability distribution in PERT, it becomes possible to draw some inferences regarding the uncertain expressions of real-life problems, however, linear approximations such as trapezoidal and triangular fuzzy numbers are frequently used (Chanas & Kamburowski 1981; Dubois & Prade 1988; Lorterapong & Moselhi 1996). Lorterapong and Moselhi (1996) developed a complete project network analysis technique by using a fuzzy set theory named FNET. This technique includes a new procedure for performing the forward and backward pass calculations of CPM with fuzzy sets in cases where the activities are dependent on one another having only finish-to-start relations, and where no lag or lead times are used between the activities. However, if other types of network dependencies, such as finish-to-finish, start-to-start or start-to-finish, and lag/lead times are used, this technique fails. In this study, it is aimed to propose a new method to be used for the full implementation of CPM with fuzzy sets, in case lag/lead times and all dependency types are used.

The details of the new method are described after introducing the basic information about fuzzy set theory and fuzzy numbers, and then an application example is carried out. The paper ends with the conclusions and recommendations for future work.

Fuzzy set theory and fuzzy numbers
In classical set theory, the membership of an element to a specified set is described by two definite and opposite situations: belonging to the set (membership degree = 1.0) or not belonging to the set (membership degree = 0.0). However, in fuzzy set theory, the membership of an element to a specified set is described by the membership degrees between 0.0 and 1.0 (Zadeh 1965; Šen 2004; Ross 2010). This provides the opportunity of modelling the uncertain expressions of real-life mathematically, performing fuzzy set operations between these uncertainties and finally reaching fuzzy results that cannot be achieved analytically otherwise.

Consider a fuzzy set A of the universe U.

\[ A = \{(x, \mu_A(x))|x \in A, \mu_A(x) \in [0, 1]\} \]

where \( \mu_A(x) \) is a function called membership function, and \( \mu_A(x) \) exactly states the grade or degree to which any element x in A is a member of the fuzzy set A.

The definition given above combines each element x in A with \( \mu_A(x) \) in the interval [0, 1] which is assigned to x. Larger values of \( \mu_A(x) \) indicate higher degrees of membership (Bojadziev & Bojadziev 1997; Han 2005; Ross 2010).

A fuzzy number is a continuous fuzzy set that possesses two properties: convexity and normality. The convexity indicates that the membership function has only one distinct peak, while the normality ensures that at least one element in the set has a degree of membership equal to 1.0. These two properties make the concept of fuzzy numbers attractive and naturally appropriate for modelling imprecise fuzzy quantities such as “approximately one week,” or “more or less than seven days”. Theoretically, fuzzy numbers can take various shapes. In modelling real-life problems, however, linear approximations such as trapezoidal and triangular fuzzy numbers are frequently used (Chanas & Kamburowski 1981; Dubois & Prade 1988). Mathematical definitions and general shapes of triangular and trapezoidal fuzzy numbers are given below:

Triangular fuzzy numbers
A triangular fuzzy number with membership function \( \mu_A(x) \) is defined by:
This set is graphically shown in Figure 1.

**Trapezoidal fuzzy numbers**
A trapezoidal fuzzy number with membership function $\mu_A(x)$ is defined by

$$
\mu_A(x) = \begin{cases} 
\frac{(x-a)}{(b-a)} & \text{for } a \leq x \leq b \\
\frac{(x-c)}{(d-c)} & \text{for } b < x < c \\
1 & \text{for } c \leq x \leq d \\
0 & \text{otherwise}
\end{cases}
$$

This set is graphically shown in Figure 2.

### CPM NETWORK CALCULATIONS WITH FUZZY SETS AND FUZZY OPERATIONS

The early/late start/finish times, total float times, criticalness of the activities and the project completion time of a network are explored by applying forward and backward pass calculations on the network. In other words, forward and backward pass calculations constitute the network calculations of CPM. In order to carry out the CPM network calculations, activity durations, activity interdependencies in the form of FS, FF, SS or SF, and lag/lead times between the activities are required. The activity durations should be predicted as invariable fixed values, unless fuzzy values are used. These fuzzy values are used when the activity durations are expressed in fuzzy values and the activity durations are not known accurately. The activity durations are described below:

$$
FEF_x = \max (FEF_p)
$$

(7)

$$
FEF_x = FES_x + FD_x
$$

(8)

$$
T_{proj} = FEF_x
$$

(9)

where $p \in P$ (the set of predecessor activities); $FES_x$, $FEF_x$, $FD_x$ are the fuzzy early start time, fuzzy early finish time and fuzzy duration of activity $x$ respectively; and $T_{proj}$ and $FEF_x$ are the fuzzy project duration and fuzzy early finish time of the last activity respectively. However, the construction project activity networks may include lag or lead times, and other dependencies such as SS and FF between activities. This problem is resolved by the following algorithm:

i. Subtract lead time from lag time with fuzzy subtraction for each activity pair having a predecessor/successor relation.

$$
FN_{pi} = [\text{fuzzy lag}_{pi} - \text{fuzzy lead}_{pi}]
$$

(10)

where $pi$ denotes the predecessor activity so that $i$ takes values depending on the number of predecessors.

ii. Add the fuzzy number calculated in step (i) with fuzzy addition to the corresponding early time of the predecessor activity. For instance, if the relation is FF between an activity and one of its predecessors, then early finish time of this activity is calculated by adding the fuzzy number calculated in step (i) to the early finish time of the predecessor activity.

$$
FEF_{si} = FEF_{pi} + FN_{pi}
$$

(11)

where $si$ denotes the successor activity. Once more, $i$ takes values depending on the number of predecessors.

iii. Fuzzy early start times of an activity are calculated by employing the fuzzy duration of this activity to the fuzzy early start times found in step (ii). However, this step is executed if the dependency is SF or FF. If the dependency is SS or FS, the fuzzy early time found in step (ii) is already the fuzzy early start time.

$$
FES_{si} = \max (FES_{pi})
$$

(12)
The procedure of fuzzy forward pass calculation described above is clarified by an application in a short example network portion (four predecessors – one successor network portion), which is shown in Figure 3.

All of the fuzzy numbers in the Figure 3 example are accepted as trapezoidal. However, the mode values, b and c, are accepted as equal to each other for the purpose of modifying the trapezoidal fuzzy numbers to triangular fuzzy numbers in order to simplify the calculations. The network consists of a single activity whose fuzzy early start and fuzzy early finish times are being searched, and four predecessor activities whose dependency and lag/lead times are being searched, and four predecessor fuzzy early start and fuzzy early finish times of activities. Fuzzy forward pass calculations of this example network are performed as follows:

**Predecessor 1 (p1):**
FES_{p1} = FES_{s1} (+) Fuzzy lag_{p1} (–) fuzzy lead_{p1}  
FES_{p1} = (5,6,6,8) {+} [(0,0,0,0) {–} (0,1,1,2)]  
FES_{p1} = (5,6,6,8) (+) (–2,–1,–1,0)  
FES_{p1} = (3,5,5,8)

**Predecessor 2 (p2):**
FES_{p2} = FES_{s2} (+) [fuzzy lag_{p2} (→) fuzzy lead_{p2}]  
FES_{p2} = (4,5,5,7) {+} [(0,1,1,2) {–} (0,0,0,0)]  
FES_{p2} = (4,5,5,7) (+) (0,1,1,2)  
FES_{p2} = (4,6,6,9)

**Predecessor 3 (p3):**
FES_{p3} = FES_{s3} (+) [fuzzy lag_{p3} (→) fuzzy lead_{p3}]  
FES_{p3} = (8,10,10,12) (+) [(0,1,1,2) {–} (0,0,0,0)]  
FES_{p3} = (8,11,11,14)

![Figure 3 Four predecessors – one successor network portion](image)

**Predecessor 4 (p4):**
FES_{p4} = FES_{s4} (+) [Fuzzy Act. Dur., S (FD_{s4})]  
FES_{p4} = (6,9,9,13) (+) (0,2,2,3)  
FES_{p4} = (6,11,11,16)

**Predecessor 5 (p5):**
FES_{p5} = FES_{s5} (+) Fuzzy Act. Dur., S (FD_{s5})  
FES_{p5} = (8,11,11,16)

This example application shows that the fuzzy early start time of the successor activity S in Figure 3 is (7,9,9,13), i.e. the early start time of the activity S is certainly between the 7th and 13th unit times (day, month, etc), and it is most plausibly at the 9th unit time from the starting date of the network.

**Backward pass calculations with fuzzy sets**

If the activity durations and lag/lead times are represented by fuzzy sets, fuzzy backward pass calculations should be performed through fuzzy operations just as in the case of fuzzy forward pass calculations. For this reason, fuzzy subtraction has been utilised in order to develop the fuzzy backward pass calculation procedure. However, a problem occurs due to the usage of fuzzy subtraction. Fuzzy subtraction produces unrealistically large uncertainties associated with fuzzy late start and fuzzy late finish times of activities.

These uncertainties accumulate quickly as the backward pass calculation progresses. Moreover, earlier activities may be assigned with negative early finish and late finish times at the end of the calculation which has no meaning from the scheduling point of view. Lorterapong and Moselhi (1996) tried to overcome this problem by developing a procedure while developing their so-called model, FNET. However, only FS relation was considered and lag/lead times were ignored in FNET. For this reason, their method has been carried one step further in this study to circumvent these limitations. The used assumptions and the developed backward pass calculation procedure are described below.

**Assumptions**
- All the values in fuzzy numbers (lower, upper and mode values – a, b, c, d) should have a positive value.
- Each value should not exceed its successor (a ≤ b ≤ c ≤ d).
- The values of the fuzzy early start time of fuzzy early finish time of an activity found by fuzzy forward pass calculation should not exceed the values of the fuzzy late start or fuzzy late finish times found by the fuzzy backward pass calculation.
- The right spread of fuzzy late times (the difference between d and c) should be at least as uncertain as their respective fuzzy early times.

**Procedure**
i. First, lag/lead times between the activities are processed. Since the operation is now the backward pass, lag times are considered just like the lead times of forward pass, and lead times are considered just like the lag times of forward pass. In other words, lag time is subtracted from lead time, with fuzzy subtraction for each
activity pair having predecessor-successor relation.

\[ FN_{si} = \{fuzzy\ lead_{si} \} \{fuzzy\ lag_{si}\} \]  \hspace{1cm} (15)

where \( si \) denotes the successor activity so that \( i \) takes values depending on the number of successors.

ii. The fuzzy number calculated in step (i) is added with fuzzy addition to the corresponding late time of the successor activity. For instance, if the relation is FF between an activity and one of its successors, then late finish time of this activity is calculated through fuzzy adding of the fuzzy number calculated in step (i) to the late finish time of the successor activity.

\[ FLF_{pi} = FLF_{pi} (+) FN_{si} \]  \hspace{1cm} (16)

where \( pi \) denotes the predecessor activity. Once more, \( i \) takes values depending on the number of successors.

iii. Fuzzy late finish times of an activity \( x \) are calculated with employing fuzzy duration of this activity to the fuzzy late times found in step (ii). However, this step is executed if the dependency is SF or SS. If the dependency is FS or FF, the fuzzy late time found in step (ii). However, this step is already the fuzzy late finish time.

\[ FLF_{pi} = \{ FLF_{si} (+) FN_{si}\} \{ relation\ is\ FS, FF \} \]
\[ FLF_{pi} = \{ FLF_{si} (+) FN_{si}\} \{ relation\ is\ SS, SF \} \]  \hspace{1cm} (17)

where \( FD_{p} \) shows the fuzzy duration of the predecessor activity in question.

iv. Final fuzzy late finish time of an activity is found with fuzzy minimisation of the fuzzy late finish times calculated in step (ii).

\[ FLF_{pi} = min (FLF_{pi}) \]  \hspace{1cm} (18)

v. The fuzzy number found in step (iv) is accepted as the preliminary fuzzy late finish time (PFLF).

vi. FEF and PFLF are compared to find which of the two fuzzy numbers has a greater right spread. Suppose that FEF is represented by \((a,b,c,d)\) and the PFLF is represented by \((g,q,e,f)\). In this case, the comparison is made between \((f – d)\) and \((d – c)\) (Lorterapong & Moselhi 1996).

\[ FLF_{p} = FEF_{p} (+) (f – d, f – d, f – d, f – d) \]
\[ FLF_{p} = (a, b, c, d) (+) (f – d, f – d, f – d, f – d, f – d) \]
\[ FLF_{p} = (a + f – d, b + f – d, c + f – d, f – d) \]
\[ FLF_{p} = (a + f – d, b + f – d, c + f – d, f) \]  \hspace{1cm} (19)

vii. If \((d – c) > (f – e)\), which means that the right spread of FEF is more uncertain, the right spread of the final fuzzy late finish time (FLF) is set equal to the right spread of FEF. In this case, FLF is calculated by Equation 19 (Lorterapong & Moselhi 1996).

\[ \text{Successor 1} \ (s1) : \]
\[ \text{FLF}_{p1} = \text{FLS}_{s1} \ (+) \{fuzzy\ lead_{s1}\} \{fuzzy lag_{s1}\} \]
\[ \text{FLF}_{p1} = (9,10,10,11) \ (+) \{0,1,1,2\} \]
\[ \text{FLF}_{p1} = (9,10,11,13) \]

\[ \text{Successor 2} \ (s2) : \]
\[ \text{FLS}_{s2} = \text{FLS}_{s2} \ (+) \{fuzzy\ lead_{s2}\} \{fuzzy lag_{s2}\} \]
\[ \text{FLS}_{s2} = (10,11,11,13) \ (+) \{0,0,0,0\} \]
\[ \text{FLS}_{s2} = (10,11,11,13) \]

\[ \text{Successor 3} \ (s3) : \]
\[ \text{FLF}_{p1} = \text{FLF}_{p1} \ (+) \{fuzzy lead_{s3}\} \{fuzzy lag_{s3}\} \]
\[ \text{FLF}_{p1} = (12,14,14,16) \ (+) \{0,0,0,0\} \]
\[ \text{FLF}_{p1} = (10,13,13,16) \]

\[ \text{Successor 4} \ (s4) : \]
\[ \text{FLS}_{s4} = \text{FLS}_{s4} \ (+) \{fuzzy lead_{s4}\} \{fuzzy lag_{s4}\} \]
\[ \text{FLS}_{s4} = (12,14,14,16) \ (+) \{0,0,0,0\} \]

All of the fuzzy numbers are taken as trapezoidal. However, mode values \( b \) and \( c \) are taken equal for the purpose of modifying the trapezoidal fuzzy numbers to triangular fuzzy numbers in order to provide simplicity in this example. The network consists of a single activity whose fuzzy late finish times are being searched, and four successor activities whose dependency and lead/lag times differ, as shown in Figure 4. Fuzzy backward pass calculations of this network are as follows:

\[ S1 \]
\[ S2 \]
\[ S3 \]
\[ S4 \]
Fuzzy backward pass calculation may sometimes produce negative values, especially for the lower and mode fuzzy values (a,b,c) or it may produce zero for the mode fuzzy values (b,c) of the activities at the beginning of the network. In the former case, negative values are converted to zero and in the latter case all the fuzzy values (a,b,c,d) are accepted as zero.

**AN EXAMPLE APPLICATION**

This section introduces an example application of the proposed fuzzy set CPM-based methodology on a hypothetical activity network. Network information and the results of the application are given in Tables 1 and 2, respectively. The network is a short and simple one, but it contains all types of network dependencies, i.e. FS, FF, SS, SF with lag and lead times. Therefore, it stands as a good example for showing the application of all of the features of CPM with fuzzy sets.

The results given in Table 2 reveal that the total float times of activities were calculated by using geometric centres of fuzzy early and fuzzy late times of the activities, and critical and uncritical activities have been determined with respect to the total float times. The calculation procedure of total float times (TF) by using the geometric centres of the fuzzy numbers is given by Equations 22 and 23 as follows (Lorterapong and Moselhi 1996):

\[
TF_x \in X = CLF_x - CEF_x
\]  

where the C designation denotes the geometric centre of the early and late times, \(x \in X\) (the set of activities), and CEF and CLF show geometric centres of fuzzy early finish and fuzzy late finish times respectively.

The geometric centre of a trapezoidal fuzzy set is calculated by Equation 23.

\[
C = \frac{c^2 + d^2 - a^2 - b^2 + c \cdot d - a \cdot b}{3 \cdot (d + c - a - b)}
\]

It should be mentioned that the activities with total float times close to zero, and with early and late times very close to one another, have been considered as critical in this study for the sake of detecting the critical path. For example, total float time, fuzzy early finish and fuzzy late finish times of activity C have been found as 1.67, (8,12,12,16) and (8,12,12,21), respectively (refer to Table 2). Therefore, activity C has been considered as a critical activity.

Another float type examined in Table 2 is the independent float. While the total float time is the amount of time that an activity can be delayed without delaying the project completion time, the independent float time is the amount of time that an activity can be delayed without delaying the start of any of its successor activities (Newitt 2008). In other words, independent float is the delay possible

</table>
for an activity if all preceding activities start as late as possible and all subsequent activities start at their earliest time. The independent float times (IF) given in Table 2 have been calculated through Equations 23 and 24.

\[ IF_x = CEF_x - CLS_x - CFD_x \] (24)

where the C designation denotes the geometric centre of the early and late times; \( x \) the set of activities; CEF, CLS, and CFD show geometric centres of fuzzy early finish time, fuzzy late start time, and fuzzy activity duration respectively (refer to Equation 23). If IF is calculated below zero, then it is accepted equal to zero as in the case of the activity network examined in the example application (refer to Table 2). Otherwise, it would be meaningless to have a negative time value.

CONCLUSIONS AND FUTURE WORK

Construction activities are performed under uncertain conditions. Various risks cause variation in activity duration, and in turn the values found by CPM, such as the activity early/late times, become uncertain. In this context, activity durations are represented by fuzzy sets and the CPM network calculations are performed by fuzzy operations through a new method developed in this study. In this method, fuzzy sets are utilised to model the uncertainty in activity durations, activity early/late times and project completion time. An example CPM application with fuzzy sets was also presented. The findings show that CPM is applicable with fuzzy sets, and the developed method operates well for modelling the uncertainty in CPM network calculations.

The representation of activity durations by fuzzy sets enables modelling the uncertainty effect. In construction projects, it is not possible to predict the duration of an activity with certainty. Predictions such as “this activity can be completed most probably between seven and ten days, but perhaps it takes 15 days maximum and 5 days minimum depending on the conditions” are frequently made. Fuzzy sets are suitable to model these kinds of linguistic propositions mathematically. Since the activity durations are represented by fuzzy sets and the network calculations are performed by fuzzy operations, the activity early/late start/finish times and the project completion time or the project duration are calculated as fuzzy sets through this new method. In other words, the effect of uncertainty on the results of CPM is modelled. Furthermore, the evaluation of activity/path criticalness is realised by using the geometric centres of the activity early/late times.

Execution of CPM by using fuzzy sets and fuzzy operations through the proposed method possesses some advantages over the traditional use of PERT, such as the following:

- While PERT takes only the critical path into account by ignoring the other activity paths, the proposed method evaluates the uncertainty in all of the activities, and accordingly on all of the activity paths.
- While PERT applies a simplification process to the estimated minimum, maximum and most likely durations in order to calculate the expected activity durations and variances, the proposed method does not require any simplifications, because the activities are represented by fuzzy sets, and CPM calculations are performed by using these fuzzy sets as a whole.

While PERT assumes that project completion time follows normal probability distribution represented by the mean and variance parameters found by adding the expected durations and variances of the activities on the critical path, the proposed method computes the project completion time as a fuzzy set through fuzzy forward and backward CPM calculations performed by using the fuzzy durations of all of the activities, both on the critical and uncritical paths.

The new method for the CPM network calculations with fuzzy sets, as proposed in this study, can also be compared with the other uncertainty analysis methods such as the Monte Carlo simulation-based models. Furthermore, it can be used for developing a fuzzy schedule risk analysis model operating with simulation, on which the authors currently focus their studies. It can also be computerised easily by utilising table processor software or computer programming languages. These issues are proposed as future work.
