ABSTRACT

Odontomas are rare pathological abnormalities which may occur at any age. It is most unusual to observe an odontoma together with supernumerary teeth, particularly if this is found in conjunction with an osteoma. This report emphasizes the underlying pathology of a case co-incidentally encountered in a 14 year old patient whose main complaint was of a painful 85 tooth.

An incisional biopsy of the area revealed the presence of mineralized tooth-related tissue resembling a complex odontoma. In conjunction with the radiographic evidence, which confirmed the presence of complex and compound odontomas as well as a number of small osteomas, a provisional diagnosis of Gardner’s syndrome was made. The syndrome is a rare autosomal disease that is difficult to treat. If a dentist suspects a patient may present with Gardner’s syndrome, the patient should be referred immediately for further medical management.

INTRODUCTION

Benign odontogenic tumours include ameloblastoma, ameloblastic fibroma, ameloblastic fibrodontoma, complex and compound odontomas.¹ Of these, the most commonly encountered in patients less than 20 years of age are the complex and compound odontomas.² These tumours are asymptomatic, slow-growing and may lead to malformation of adjacent developing teeth and malocclusion.

The complexity of odontomas has been studied and analyzed for many years. One example is that of supernumerary teeth developing largely within the maxillary permanent dentition and in conjunction with odontomas.³ These are usually asymptomatic, but may be associated with pathologic implications. One such manifestation is that of Gardener’s Syndrome if the odontoma is also associated with the presence of osteomas.⁴⁻¹⁰ This is a life-threatening condition and it is essential that the presenting signs are not missed.

CASE REPORT

A 14 year-old female patient presented at the Wits Oral Health Centre complaining of a painful primary tooth (85) which appeared to have prevented eruption of the permanent successor, causing a severe malocclusion.

No medical problems were reported. Extra-oral findings revealed no abnormalities. Facial asymmetry was not detected (Fig 1). Intra-oral examination revealed missing premolars together with carious and painful mandibular primary second molars (Figs 1-5). An anterior cross bite involving tooth 42 was noted together with a deep overbite (Fig 2). The gingiva surrounding the painful tooth (85) was swollen with a buccal exudate (Fig 4).

In pursuit of accurate diagnosis and an appropriate treatment plan, further investigations included a panoramic radiograph, a lateral cephalogram and a cone-beam volumetric tomogram (CBCT).
The panoramic radiograph revealed the presence of numerous unerupted and retained deciduous teeth, compound and complex odontomas (bi-mandibular) and a well circumscribed radiolucent lesion resembling a radicular cyst at the apex of the right mandibular deciduous second molar tooth. Several of the unerupted teeth were supernumeraries. The angles of the mandible were deformed by presence number of ectopic teeth and small osteomas (Fig 4). The lateral cephalogram revealed a growth on the inion of the occipital bone (Fig 5).

The patient was classified as having a normal skeletal and dental class 1 profile (Fig 5). However, the bone deformities together with the presence of unerupted supernumeraries, ectopic teeth, osteomas and compound and complex odontomas suggested a diagnosis of Gardner’s syndrome, despite the apparent absence of visible epidermoid cysts of the skin.

The CBCT scan confirmed the presence of carious lesions of the teeth, together with multiple radio-opacities on the left angle and ramus of the mandible (Fig 6).

These displayed the appearance of osteomas, thereby confirming the provisional diagnosis of Gardner’s syndrome.
Referral for colonoscopy was essential for final confirmation of Gardner’s Syndrome and the surgical removal of colonic polyps. Recurrence of the odontomas and osteomas is not uncommon and would require possible further surgical intervention. Since there is no cure for Gardner’s Syndrome, prevention of cancer is the primary aim in management.12

Acknowledgement

Sincere thanks to Professor E Rikhotso and his team from the Maxillo-facial and Oral Surgery Department for sharing the biopsy information with us. The authors would also like to thank Professor Dandajena, Dr Moshaoa and Professor Evans of the Orthodontic Department for their opinion on the orthodontic treatment approach of this case.

Do the CPD questionnaire on page 153

The Continuous Professional Development (CPD) section provides for twenty general questions and five ethics questions. The section provides members with a valuable source of CPD points whilst also achieving the objective of CPD, to assure continuing education. The importance of continuing professional development should not be underestimated, it is a career-long obligation for practicing professionals.

Online CPD in 6 Easy Steps

1. Go to the SADA website www.sada.co.za.
2. Log into the ‘member only’ section with your unique SADA username and password.
3. Select the CPD navigation tab.
4. Select the questionnaire that you wish to complete.
5. Enter your multiple choice answers. Please note that you have two attempts to obtain at least 70%.
6. View and print your CPD certificate.
