Figure 2 and 3 revealed an ill-defined radiopaque lesion of the right maxilla extending into the maxillary sinus, the nasal cavity, displacing the nasal septum, the infratemporal fossa and inferiorly into the hard palate and oral cavity. The coronal soft tissue window (Fig. 4) shows the lesion extending superiorly into the ethmoid sinus and orbital floor. Non-contrast axial bone window (Fig. 5) shows a large multilocular expansile lesion within the maxilla. A histological diagnosis of a plasma cell myeloma (Plasmacytoma) was made. This is an unusual lesion which some authorities believe to be unrelated to multiple myeloma even though the two are microscopically indistinguishable. The lesion affects only a single bone. Infrequently, it is seen in soft tissue, in which case, the term extramedullary plasmacytoma is used. The criteria for establishing a diagnosis of solitary plasma cell myeloma are not well defined. Multiple myeloma usually runs an invariably fatal course within two years, or at least becomes widely disseminated in that period. Christopherson and Miller, in reviewing 51 cases of solitary plasma cell myeloma, found a predilection for the sixth decade, although the age range of the patients was from 19 months to 72 years. Males were affected more frequently than females, as in multiple myeloma. The authors also stated that all cases surviving for three years without evidence of dissemination or “metastasis” may be considered true examples of solitary myeloma. Radiographically, the lesion may be seen as a well-defined, unilocular radiolucency with no evidence of sclerotic borders or as a ragged radiolucency similar to multiple myeloma. There is nothing pathognomonic or even characteristic of the roentgenographic features of solitary plasmacytoma. Plasmacytoma are usually treated with radiation therapy. Lesions have been surgically excised with good results, although this is not the preferred treatment in most instances. Unfortunately, when patients with plasmacytoma of bone are observed on a long-term basis most will develop multiple myeloma.
