Intraradicular rehabilitation of a necrotic, immature tooth using MTA, a fiber post and composite resin - A case report

ABSTRACT

Endodontic treatment of necrotic, immature teeth with open apices can present challenges to debridement, disinfection, and optimal obturation. These teeth may have widely flared canals and thin radicular dentinal walls that are susceptible to fracture. Management of the open apex can be performed using a mineral trioxide aggregate (MTA) apical plug. To ensure a better prognosis in such structurally compromised teeth, internal radicular reinforcement using fiber posts and a self-adhesive cement has been suggested. The present case report illustrates the management of a necrotic, immature maxillary right central incisor in a 10-year-old patient using the MTA apical barrier technique and canal reinforcement using a fiber post.

Keywords
Apexification, calcium hydroxide, fiber post, mineral trioxide aggregate.

INTRODUCTION

Studies on the prevalence of dental trauma have shown 20%-30% of children sustain traumatic dental injury to their permanent dentition.¹ The majority of these incidents occur before root formation is complete and may result in pulp inflammation or necrosis. With the loss of vitality and subsequent arrested root development, the open and sometimes divergent apical morphology, along with thin and fragile dentinal walls, represents both an endodontic and restorative challenge. It is imperative that these structurally compromised teeth are preserved in the young patient, as alternative treatment options such as implant-supported restorations or fixed prostheses require completion of craniofacial growth for acceptable outcomes.² Although regenerative procedures are the current protocol, clinical translation is relatively new in its inception and requires further research. Therefore, we chose a current and clinically reliable procedure for the treatment of this presenting case.

Thus, the purpose of this case report is to discuss the intricacies of treatment of a fractured, necrotic, immature maxillary central incisor using the MTA apical barrier technique and fiber post placement.

CASE REPORT

A 10-year-old male patient with non-contributory medical history was referred for evaluation and treatment of his fractured immature maxillary right central incisor. He had suffered a traumatic sporting injury with loss of the coronal fragment of the tooth and subsequent loss of vitality 12 months prior. Therapeutic dressings of calcium hydroxide had been applied by his general dentist at the local community clinic to induce apical closure. However, patient compliance regarding regular attendance had been poor. Clinical examination revealed a complicated crown fracture of the maxillary right central incisor with evidence of an interim glass ionomer restoration over the access cavity (Fig. 1). Periapical radiographs demonstrated an incompletely formed root apex with normal apical tissues. There was evidence of an intracanal calcium hydroxide dressing. A root development stage 2 to 3 was established³ (Fig. 2).

Fig. 1

Clinical examination revealed a complicated crown fracture of the maxillary right central incisor with evidence of an interim glass ionomer restoration over the access cavity (Fig. 1). Periapical radiographs demonstrated an incompletely formed root apex with normal apical tissues. There was evidence of an intracanal calcium hydroxide dressing. A root development stage 2 to 3 was established³ (Fig. 2).

Fig. 2
Due to a history of poor compliance in attending regular appointments, the mineral trioxide aggregate (MTA) apical barrier technique (ProRoot MTA; Dentsply Tulsa Dental, Johnson City, TN, USA) was chosen as the most viable treatment option. Consent from both the child and attendant parent was obtained with a detailed explanation of treatment rationale. On the first visit, root canal treatment was initiated. Local anaesthetic infiltration was administered using 2% lidocaine with 1:80 000 epinephrine (Lignospan Special, Septodont, Saint-Maur-des-Fossés, France) over the maxillary right central incisor.

Following rubber dam application, access to the pulp chamber was gained. Working length was then established using an apex locator (Root ZX) (J Morita MFG Corp., Kyoto, Japan), with accuracy further confirmed with a periapical radiograph (Fig. 3).

Cleaning and shaping was carefully performed using large stainless-steel K-files (Dentsply Maillefer, Baillagues, Switzerland), supplemented with copious irrigation using 1% sodium hypochlorite (NaOCl) (Endosure 1% Hypochlor, Dentalife, Victoria, Australia). After drying with sterile, ab-
sorbent paper points, the root canal system was dress-
ed with calcium hydroxide paste (Ca(OH)$_2$) (Calxyl OCO
PRÄPARATE® GMBH, Dirmstein, Germany) using a lentulo
spiral. A temporary coronal restoration was established
with a sterile cotton pellet, Cavit (ESPE, Seefeld, Germany)
and Fuji IX glass ionomer cement (GC, IL, USA). The pa-
tient was scheduled for a second visit after six weeks.

The tooth was asymptomatic during the entire post-op-
erative period, and the provisional restoration was still
intact at the second visit. Local anaesthesia was ac-
complished with Lignospan Special. After isolation with
rubber dam, the provisional restoration was removed
from the access cavity.

A copious amount of 1% NaOCl was ultrasonically acti-
vated to remove the Ca(OH)$_2$ paste from the canal. Before
MTA application, the canal was irrigated with 15% ethyl-
enediaminetetraacetic acid (EDTA) (Endosure EDTA 15%-
Solution, Dentalife, Victoria, Australia) to remove the smear
layer and again with 1% NaOCl. The root canal was then
dried with sterile absorbent paper points. White ProRoot
MTA was mixed with sterile water according to the manu-
facturer’s instructions.

The application of an apical barrier of 4-5mm of MTA was
completed using a Lee block (San Francisco, USA) and
Buchanan Pluggers (Sybron Endo, Orange, CA, USA).
It was further compacted using indirect ultrasonic com-
paction. Thus, a 5mm apical plug was obtained and a
radiograph exposed to verify density and position of the
MTA plug (Fig. 4). After application of MTA, a paper point
moistened with sterile water was left in contact with the
MTA plug and the access cavity sealed temporarily using
Cavit and Fuji IX glass ionomer cement.

At the next visit 24 hours later, the provisional access
cavity restoration was removed under rubber dam appli-
cation. A Buchanan’s plugger was then inserted to con-
firm the complete setting of the MTA apical plug. The root
canal was then irrigated with 1% NaOCl, followed by
saline and dried with paper points. A Rely-X Fiber Post
(3M ESPE, Germany) was trimmed and cemented with
Rely-X Unicem Self-Adhesive Universal Resin Cement (3M
ESPE, Germany) - shade A2. No additional instrumen-
tation was needed to accommodate the post due to the
widely flared canal walls, thus preserving intraradicular
dentine. Composite aesthetic restoration was completed
using AdperTM ScotchbondTM Multi-purpose adhesive
(3M ESPE, Germany) and a layered stratification tech-
nique incorporating Filtek Supreme XTE Universal Rest-
orative Composite (3M ESPE, Germany) A2 body and
A1 enamel shades. Soflex discs (3M ESPE, Germany)
were used for aesthetic recontouring and polishing.

Occlusion was adjusted for centric and eccentric excurs-
sions. A final post-operative radiograph was taken (Fig.
5). The patient and his parents were satisfied with the
aesthetic appearance of the restoration (Fig. 6). Use of
a custom fitted mouthguard was advised for any contact
sports to mitigate against any possible future fracture.

It was further reiterated that the treatment provided is to
ensure preservation of the tooth till craniofacial growth is
completed, hence due care is advised.

The patient was recalled after 12 months. He reported
that no symptoms had occurred and no complications were
noted. The restoration still appeared acceptable (Fig. 7).
A periapical radiograph demonstrated that the fiber post
and restoration remained satisfactory with normal peri-
apical tissues (Fig. 8).

Apexification is defined as a method to induce a calcified
barrier in a root with an open apex or the continued apical
development of an incompletely formed root in immature
teeth with necrotic pulps. Traditionally, the most common-
ly used material for apexification is calcium hydroxide.
Success rates are reported to be in the mid 90% range.\textsuperscript{5} Disadvantages to this technique include the need for multiple appointments, extended treatment time, possible patient compliance issues and susceptibility to re-infection.\textsuperscript{6} There also exists the possibility of weakening of tooth structure\textsuperscript{7,8,9} with subsequent root fracture.

Considering these significant disadvantages, an alternative treatment to traditional apexification with calcium hydroxide may offer a better prognostic outcome. Studies have indicated MTA as an alternative to calcium hydroxide.\textsuperscript{10,11} The advantages of MTA include excellent biocompatibility,\textsuperscript{12} induction of hard tissue,\textsuperscript{11} and good sealing properties.\textsuperscript{13,14} Additional advantages include a shorter treatment time and development of a good apical seal.\textsuperscript{15,16}

Despite these advantages, the root canal walls in these teeth remain thin, weak, and susceptible to fracture. Thus, restorative protocols able to reinforce the root architecture are important.\textsuperscript{17,18} It has been hypothesized that filling root canals with an adhesive material with a similar elastic modulus to dentine could improve the fracture resistance and stress distribution in immature teeth.\textsuperscript{13,18} Materials which have a modulus of elasticity similar to dentine enable the equitable distribution of forces along the root canal walls. Several materials have been used in an attempt to reinforce teeth, with composite resin and fiber posts showing promise.\textsuperscript{20}

Composite resin has the ability to bond to root dentine walls, increasing the strength of the roots.\textsuperscript{19} Unfortunately, it has relatively low strength under tensile stress.\textsuperscript{21} Studies have also shown that thermocycling might significantly reduce the flexural strength of composite.\textsuperscript{22,23,24} An alternative to increase fracture resistance would be the use of fiber posts.\textsuperscript{15,25-27} Fiber posts have a modulus of elasticity similar to dentine and can be adhesively bonded to dentine, decreasing the risk of restorative failure and supporting tensile stress more effectively.\textsuperscript{22,23,24} Fiber posts might also more evenly distribute forces along the root, reducing stress concentrations.\textsuperscript{25,26}

Cementation procedures using self-adhesive resin cements are simpler than conventional bonding procedures used in root canals. Additionally, self-adhesive resin cements appear to have low shrinkage due to their viscoelastic properties.\textsuperscript{30} Polymerization shrinkage is also reduced by a lower volume of material as the fiber post occupies most of the space in the root canal. In this case, no additional intraradicular dentine removal was required to accommodate post cementation, further maintaining structural integrity of the tooth.

**CONCLUSION**

Management of a necrotic, immature, and structurally compromised tooth through an approach employing the use of the MTA apical barrier technique and reinforcement with a fiber post can be a simple and efficient procedure with excellent aesthetic and functional results.
