ABSTRACT
Composites of LDPE filled with different amounts of alumina Al₂O₃ were prepared using co-mixing technique and melt-mixing. This technique, which is easy, non-toxic and inexpensive, has been successfully used in our laboratory for different polyolefins/metal oxides nanocomposites elaboration. Samples containing 0.5, 1 and 2 wt% of alumina, were prepared by melt-mixing at 190 °C without any chemical treatment or coupling agent. The effect of alumina treatment was studied. The Al₂O₃ was first co-mixed with the stearic acid then added to the polymer. The stearic acid melts at 70 °C, thus ensuring the dispersion of the covered filler particles into the polymeric matrix, which leads to better experimental results. The morphological characterization was carried out by scanning electron microscopy (SEM) and atomic force microscopy (AFM). The thermal properties were investigated by thermogravimetric analysis (TGA). The electrical conductivity was also studied. The microstructure-properties relationships were also investigated. The composites prepared with the co-mixed Al₂O₃ were compared to those prepared with the neat Al₂O₃. The thermogravimetric (TGA) results showed an enhancement of 55 °C in the thermal stability for the LDPE/Al₂O₃ composition containing 1 wt% of treated Al₂O₃. The electrical conductivity results showed also an optimum value of 6.6×10⁻⁴ Ω⁻¹ cm⁻¹ for the same composition.

Composites, LDPE, Al₂O₃ nanoparticles, stearic acid, co-mixing method.

1. Introduction
The preparation of composite materials with reinforcing fillers is one of the successful methods used to improve the properties of polymers. The idea is to incorporate the filler nanoparticles into the polymer matrix. The properties of the resulting polymer/filler composites depend on the characteristics, i.e. dimensions, shapes, etc., of the fillers, and also on the interfacial bonding strength. Due to their good specific properties, this kind of materials has attracted great interest. Many different materials have been used as fillers for polymers. Thus, glass fibres, and more recently, natural fibres have been used in the preparation of polymer nanocomposites. But the addition of nanosized inorganic particles has also shown to be very useful in the enhancement of thermal and mechanical polymer properties. For instance, clay has been widely used in the preparation of composites for polymers such as PP, PVDF or its blends with poly (methyl methacrylate) PMMA. Finally, metallic oxides (ZnO, MgO, TiO₂, Al₂O₃, CuO, etc.) are being explored as potential polymer fillers in the preparation of nanocomposites. Thus, for instance, Ren GuiHua et al. studied the dielectric, optical and thermal properties of low-density polyethylene/titania composites. Authors demonstrated that an optimum combination of mechanical and hydrophilic properties of low-density polyethylene for water-based applications can be achieved by filling the matrix with 1–3 volume % of TiO₂ particles, 0.5 µm in size.

In this study, we present the results obtained in the preparation and characterization of LDPE-based nanocomposites, prepared with both pure and stearic acid treated Al₂O₃.

Low-density polyethylene (LDPE) is a commercial polymer with a wide range of applications. This polyolefin presents high flexibility, good processability and excellent resistance to dilute and concentrated acids, alcohols, esters and bases. Alumina Al₂O₃ was selected as a filler for the LDPE due to its excellent dielectric properties. Its surface treatment with stearic acid was carried out to improve the quality of polymer/filler interfaces, thus ensuring compatibility and good dispersion of the filler into the polymeric matrix.

Several researchers have studied the behaviour of the LDPE/Al₂O₃ nanocomposites. Thus, Si-Jiao Wang et al. reported...
that the modified nano-$\text{Al}_2\text{O}_3$ particles with vinyl silane coupling can be homogeneously dispersed in LDPE matrix. Effects of $\gamma$-radiation on dielectric properties of LDPE–$\text{Al}_2\text{O}_3$ nanocomposites have been studied by F. Ciuprina et al.\textsuperscript{17} Finally, O.K. Mallem\textsuperscript{18} has investigated the physicochemical properties of LDPE/$\text{Al}_2\text{O}_3$ and PP/$\text{Al}_2\text{O}_3$ compositions.

2. Experimental

2.1. Materials

Low-density polyethylene LDPE (Sabic), from Saudi Basic Industries Corporation, was used as received. Density = 961 kg m$^{-3}$. Melt flow rate = 0.7 g 10 min$^{-1}$ (at 190 °C and 2.16 kg) Alumina $\text{Al}_2\text{O}_3$ was supplied by Aldrich Company. Molecular weight = 101.96 g mol$^{-1}$. Particle sizes about 100 µm. Stearic acid was supplied by Merck. Bulk density: 400–500 kg m$^{-3}$.

2.2. Mechanical Treatment of $\text{Al}_2\text{O}_3$

In the present work we deal with the use of the co-mixing method as a fast, inexpensive and non-harmful physical technique. In order to reduce the size of the alumina filler, it was ground using coffee grinder of Clatronic Bomann (see Fig. 1).

The use of the stearic acid, which is a lubricant for certain polymers, facilitates the dispersion of the $\text{Al}_2\text{O}_3$ particles into the LDPE matrix.

The presence of agglomerations in LDPE/$\text{Al}_2\text{O}_3$ composites conventional elaboration techniques led us to use this innovative method. Properties were improved and no agglomerations were observed.

For the preparation of some samples, the $\text{Al}_2\text{O}_3$, was mechanically modified with stearic acid using the co-mixing method in order to improve the compatibility between the matrix (LDPE) and the filler ($\text{Al}_2\text{O}_3$). Thus, the $\text{Al}_2\text{O}_3$ and the stearic acid at 50/50 wt% (each filler particle must be covered by the stearic acid in order to facilitate its dispersion into the LDPE matrix) were co-mixed.

2.3. Nanocomposites Preparation

Two series of compositions with different filler contents were prepared, one using the neat $\text{Al}_2\text{O}_3$, and the other one the stearic acid (treated one). The samples classified as ‘BNA’ were those prepared using the neat filler, whereas ‘BA’ designs the compositions prepared with the treated one. For this purpose, either the neat $\text{Al}_2\text{O}_3$, or the mixture $\text{Al}_2\text{O}_3$/stearic acid were added to the LDPE in proportions of 0.5, 1 and 2 wt% by using a Brabender plastograph. The working conditions were the following: rotation speed = 30 rpm, temperature = 190 °C. The total working time was 10 min: 3 min for the LDPE, in order to lower the viscosity, and then, 7 min more once the filler was added, to well disperse it into the polymeric matrix.

The different prepared formulations are included in Table 1.

3. Characterization

3.1. Morphology

The microstructure of the neat LDPE and the LDPE/$\text{Al}_2\text{O}_3$ composites was investigated by scanning electron microscopy using an XL 30 ESEM equipment. The samples were analyzed without metallization of their surfaces.

In order to evaluate the efficiency of the stearic acid in covering the filler particles, the atomic force microscopy (AFM) technique has been used. The images were recorded using an AXIOSCOP 40 microscope with a frequency of 1 Hz and at a scale of 50 µm. The RMS roughness (root-mean-square height deviation) of the samples was obtained directly from the software of the AFM.

3.2. Thermal Properties

The thermogravimetric analysis (TGA) was carried out on a TGA 4000 instrument (Perkin Elmer), working in a nitrogen atmosphere. The tests were run at a heating rate of 20 °C min$^{-1}$ in the temperature range 25–600 °C.

3.3. Dielectric Properties

The dielectric measurements were carried out using a Hioki 3532 Hi-Tester using the four-point method.

4. Results and Discussion

4.1. AFM Microscopy

The AFM topographic images of the untreated and treated $\text{Al}_2\text{O}_3$, are represented in Fig. 2a and Fig. 2b, respectively. It is observed that the root-mean-square RMS value decreased from 334.05 nm to 63.25 nm for the treated particles.

4.2. SEM Microscopy

The micrographs of the different compositions are presented...
in Fig. 3 which shows the effect of the incorporation of 1 wt% Al$_2$O$_3$ in both compositions, BNA1 (Fig. 3b) and BA1 (Fig. 3c) compared to the neat LDPE (Fig. 3a). The micrographs reflect a more coarse dispersion of the filler into the matrix in case of not modified Al$_2$O$_3$ (Fig. 3b) and a good dispersion for the modified one (Fig. 3c). These results agree with those obtained in the optical and AFM microscopy studies. The alumina particles are well dispersed in the matrix due to good interaction between the filler particles and the polymer.

4.3. Thermogravimetric Analysis (TGA)

The thermal stability parameters, including initial decomposition temperature (IDT) and thermal degradation temperature (Td), were determined from the TG curves (Fig. 4a and Fig. 4b). From these figures, it is clear that the IDT value of the pristine LDPE is 390 °C, while the value for the composite with 1 wt% of treated Al$_2$O$_3$ is about 445 °C. Thus, this composite material presents an enhancement in its thermal stability of about 55 °C. In literature, there are several reports on the thermal stability of some polymer/filler composites was reported.$^{19,20}$

4.4. Dielectric Properties

The inorganic nanofillers have a strong influence on the permittivity of the resulting composites. Figure 5 shows the variation of the permittivity as a function of the Al$_2$O$_3$ loading for the studied composites. It can be seen that the composites values first increase with the increase of the filler load and then decrease, with an optimum value of 5.3.10$^{-7}$ Ω$^{-1}$ cm$^{-1}$ at 1 wt% of the untreated filler and 6.6.10$^{-7}$ Ω$^{-1}$ cm$^{-1}$ for the 1 wt% of treated one.

5. Conclusions

LDPE/Al$_2$O$_3$ composites were successfully prepared using the co-mixing method and a Brabender plastograph. Part of the
samples was prepared with Al₂O₃ modified by stearic acid, in order to achieve a better dispersion of the filler in the polymer matrix.

The morphological study results showed that, in case of the samples prepared with modified Al₂O₃, the stearic acid passed to the melt state and covered the Al₂O₃ particles ensuring a homogeneous dispersion of the treated filler into the matrix. This is an indication of the efficiency of the used method. This is confirmed by the AFM results, in which the roughness decreased from 334.05 nm to 63.25 nm for the treated Al₂O₃, in samples compared to the ones prepared with the not treated one.

Thermogravimetric analysis showed that 1 wt% of treated alumina has significantly improved the thermal stability of the composite by 55 °C.

The electric conductivity measurements show that the permittivity first increases and then decreases with an increase of the filler load, with an optimum value of 5.3.10⁻⁷ Ω⁻¹ cm⁻¹ for 1 wt% of the untreated filler and 6.6.10⁻⁷ Ω⁻¹ cm⁻¹ for 1 wt% of the treated one.

This result leads to the conclusion that the incorporation of 1 wt% of the treated Al₂O₃ improved significantly the thermal stability of the LDPE/Al₂O₃ composites and their electric conductivity.
