Reducing bullying in schools by focusing on school climate and school socio-economic status

Lolita Winnaar, Fabian Arends and Unathi Beku
Education and Skills Development Research Programme, Human Sciences Research Council, Pretoria, South Africa
lwinnaar@hsrc.ac.za

This paper is a secondary analysis, using data from the South African 2015 cycle of the Trends in International Mathematics and Science Study (TIMSS). TIMSS is a trend study that assesses Mathematics and Science achievement and is designed to measure changes in the education system over time. The participants of the study included 12,514 learners from 292 schools, where a national sample of schools and learners are selected, making the study nationally representative. A multiple regression was conducted to respond to the main aims of the study, which is, firstly, to investigate the association between school climate and the prevalence of bullying in schools. Secondly, to determine if the socioeconomic status of the school is associated with incidences of bullying at the school. The results show that learners are less likely to be bullied when they feel a sense of belonging to the school they attend, they are confident, and when they are constantly engaged in the classroom. A significant gender bias exists where boys are bullied more often than girls. It has also been found that students who are often bullied obtain a significantly lower score in Mathematics than their counterparts. The findings demonstrate the need for schools to monitor the nature and frequency of bullying, so that targeted interventions can be designed, implemented and monitored on a regular basis.

Keywords: bullying; school climate; school factors; school violence, South Africa; TIMSS 2015

Introduction
Burton and Leoschut (2013) argue that to some extent, schools are miniature versions of the surrounding community, and hence that the risk factors experienced in the community increases the schools’ predisposition to violence in the school environment. In schools globally, approximately 246 million boys and girls are exposed to some form of bullying annually (Greene, Robles, Stout & Suvilaakso, 2013). More frequently, students are becoming desensitised to issues of crime and violence, because these have become a common social feature (Burton & Leoschut, 2013). This is a trend observed globally (Makota & Leoschut, 2016; Organisation for Economic Co-operation and Development [OECD], 2017). Following evidence of widespread incidences of bullying globally, developed and emerging economies need to look closely at strategies that will ensure building strong partnerships between schools, parents and communities, and reducing the negative and enduring impacts of bullying. Education departments have put measures in place in the hope of reducing levels of bullying in schools, however, a more holistic approach is required, where issues of school climate become the focus, since bullying and school-based violence occur mostly in schools with an unhealthy climate (Waasdorp, Pas, O’Brennan & Bradshaw, 2011).

Literature Review
Bullying is an element of school based violence; it involves aggressive behaviour intended to harm an individual who is less dominant physically or psychologically (Mullis, Martin, Foy & Arora, 2012). It has become a topic of international concern over the last 30 years (Smith, 2011), and in this respect, the occurrence of bullying and violence in South African schools is not isolated. Studies like TIMSS have shown increased levels of bullying in schools (Reddy, Prinsloo, Arends, Visser, Winnaar, Feza, Rogers, Janse van Rensburg, Juan, Mthethwa, Ngema & Maja, 2012) from 16 per cent in 2003 to 28 per cent in 2011 (Mullis et al., 2012), with a slight drop of two percent, seen in 2015 (Zuze, Reddy, Visser, Winnaar & Govender, 2018). TIMSS, being an international study, with a methodology that allows for cross country comparisons, shows that the percent of learners exposed to bullying in South Africa is double that of the international average (Mullis, Martin, Foy & Hooper, 2016). Furthermore, the Council for Justice and Crime Prevention found that not much has changed in terms of bullying in South African schools, since their previous school violence study was completed in 2008 (Burton & Leoschut, 2013).

Studies like the TIMSS found significant associations between bullying and Mathematics achievement (Mullis et al., 2012), with average score differences of 68 more points for those learners who have very little or no exposure to incidences of bullying in school (Reddy, Visser, Winnaar, Arends, Juan, Prinsloo & Isdale, 2016). This is an important finding, since academic achievement is a vital indicator to measure in order to track learners’ successful progress through the education system (Frempong, Reddy & Kanjee, 2011).
The relationship between bullying and school climate

Researchers such as Catherine Bradshaw, Clifford Shaw, Henry McKay, Chiaki Konishi and Sara Laftman have noted that school climate is related to bullying (Konishi, Miyazaki, Hymel & Waterhouse, 2017; Laftman, Östberg & Modin, 2017; Mitchell, Bradshaw & Leaf, 2010; O'Brien, Bradshaw & Sawyer, 2009; Shaw & McKay, 1942). Whilst definitions differ across various studies, there is agreement that school climate is a multi-dimensional index of the school’s intangible factors that represent the overall social atmosphere of the school. These intangible factors include emphasis on academic success, disciplinary problems, incidences of bullying and challenges faced by teachers (Mullis et al., 2012). Low incidences of bullying are a result of a healthy school climate. In contrast, high incidences of bullying are a result of an unhealthy school climate (Finn, 1989; Mullis et al., 2012; Shaw & McKay, 1942). These results are corroborated by recent research, which found that schools with a healthier school climate (emphasis on academic success, fewer disciplinary problems, fewer incidences of bullying, and fewer challenges faced by teachers) had higher average achievement scores (Zuze et al., 2018). Lower incidences of bullying are also associated with commanding stances to school discipline, a greater sense of belonging, high levels of achievement and peer encouragement (Wang, Vaillancourt, Brittain, McDougall, Krygsman, Smith, Cunningham, Haltigan & Hymel, 2014).

In analysing the relationship between bullying and school climate, the study operationalises the Social Disorganisation Theory and the Identification and Participation Model. Researchers (Bradshaw, Sawyer & O’Brennan 2009; Konishi et al., 2017) have expanded on how a poor school climate can have an adverse effect on bullying. According to the Social Disorganisation Theory (Shaw & McKay, 1942) particular school-level factors, such as school discipline and safety and school emphasis on academic success, are important indicators of school climate. Additionally, school climate is inversely related to bullying (Bradshaw et al., 2009). Moreover, a negative school climate is related to high levels of bullying (Laftman et al., 2017; Mitchell et al., 2010; O’Brien et al., 2009; Shaw & McKay, 1942).

Similarly, the Identification-Participation model (Finn, 1989) suggests that school climate and peer groups facilitate a sense of identification and participation, which in turn results in a positive school climate (Finn, 1989). A positive school climate encourages positive interaction between peers and teachers. According to Finn (1989), students need to identify with the school; feel that they belong to the school; and believe they are welcomed, respected and valued by others.

Conversely, a school with a negative school climate is characterised by fear and intimidation and has harmful implications for student engagement and learning (Finn, 1989). Furthermore, the Identification-Participation model notes that bullying victims often lack a sense of belonging, and they feel unsupported and unwelcomed by both their peers and the teachers. This results in a process of disengagement that is characterised by low self-esteem, social anxiety, social avoidance, absenteeism and academic withdrawal (Finn, 1989). Studies by other researchers found similar results (Brand, Felner, Shim, Seitsinger & Dumas, 2003; Goodenow & Grady, 1993; Ma, 2003; Springer, Cuevas Jaramillo, Ortiz Gómez, Case & Wilkinson, 2016).

In light of these findings, it is not surprising that the TIMSS results found significant associations between bullying and Mathematics achievement (Mullis et al., 2012), with average score differences of 68 points higher for learners who have very little or no exposure to incidences of bullying in school (Reddy et al., 2016).

The relationship between bullying and socio-economic status (SES)

While bullying across schools is a widespread phenomenon, there is evidence that schools with a low SES experience higher incidences of bullying compared to medium and high SES schools. Studies have documented that schools with a low SES experienced higher incidences of bullying and discipline problems compared to schools with medium and high SES (Jansen, Verlinden, Dommisse-Van Berkel, Mieloo, Van der Ende, Veenstra, Verhulst, Jansen & Tiemeier, 2012; O’Brien et al., 2009; Wolke, Woods, Stanford & Schulz, 2001).

Low SES schools experience resource scarcity and competing interests thus school leadership has to decide which interests to prioritise amidst these competing interests. As a result, intangible school factors often receive little to no attention (Jansen et al., 2012; O’Brien et al., 2009; Wolke et al., 2001). A South African study by Zuze, Reddy, Juan, Hannan, Visser and Winnaar (2016) found similar results. They found that more than half of learners attending low SES schools stated some form type of bullying on a weekly basis (Zuze et al., 2016).

In South Africa, the National Norms and Standards for School Funding (NNSSF) policy is used to assign funds to schools to address equity in schools (Dass & Rinquest, 2017). The Department of Basic Education has demarcated all schools in the country into five poverty rankings, based on physical and infrastructural resources of the school and the area surrounding the school, (Dass & Rinquest, 2017) in order to adequately assign public funds to schools (Department of Education, 2006). As part of the government’s pro-poor strategy to
support education, schools in the first three poverty rankings, referred to as no-fee public schools, receive subsidies that make it possible to exempt learners from paying fees. The fourth and fifth ranking are referred to as fee-paying schools (Dass & Rinquest, 2017). For the purposes of this study, these two Department of Basic Education (DBE) assigned poverty rankings for public schools will be used as a proxy for the socio-economic status of the school (Van der Berg, 2008).

Socio-economic status of the school has been measured by a number of different authors in a number of different ways. The most common way is an aggregated measure of the home SES measure to the school level which is often composed of resources in the home (Lim & Gemici, 2011; Taylor & Yu, 2009), parental education (Lim & Gemici, 2011), and parental income (McKenzie, 2003); to mention a few. Research determining associations between SES and bullying with some findings showing no significant associations (Veenstra, Lindenberg, Oldehinkel, De Winter, Verhulst & Ormel, 2005), and some showing significant relationships (Wolke et al., 2001).

Conceptual Framework for Bullying, School Climate and School Socio-Economic Status
Following the work of Finn (1989), Mullis et al. (2012) and Shaw and McKay (1942), we take into account principal and learner perceptions of school climate as well as the SES of the school as factors that contribute to incidences of bullying in schools. School climate is defined as the intangible factors that make up the health of the schooling environment (Mullis et al., 2012). A school with a healthy climate is characterised by safety and orderliness, and high emphasis on academic success. Learners feel as though they belong to the school, they have confidence in their ability and are engaged within the classroom. As a result, a healthy school climate is characterised by low levels of bullying within the school (Finn, 1989; Mullis et al., 2012; Shaw & McKay, 1942).

Schools that have low levels of bullying are also characterised by a high Socio-Economic Status. They are well resourced, secure and can promote an engaged learning environment. Figure 1 displays the relationship amongst bullying, school climate and school socio-economic status.

Figure 1 Conceptual model for the relationship between bullying, school climate and school socio-economic status.
Research Question
The aims of the current paper are twofold namely: to determine the school climate factors, from the perceptions of both the learner and principal, that would reduce incidences of bullying in schools. Secondly, to determine if incidences of bullying are higher depending on the socio-economic status of school that learner attend. These aims will be addressed by responding to the following research questions:
1. How are learner perceptions of school climate associated with incidences of bullying in schools?
2. How are principal perceptions of school climate associated with incidences of bullying in schools?
3. How do incidences of bullying vary for schools from different school socio-economic status (SES)?

Method
Data Source and Sample
This paper utilises data extracted from the TIMSS South Africa study which was conducted in 2015 by the International Association for the Evaluation of Educational Achievement (IEA). TIMSS is a trend study that measures Mathematics and Science performance and conducted every four years, with the main purposes being to track the performance of a country’s education system over time.

Learner assessment tests, which were closely aligned to the South African curriculum, were administered to the learners for both Mathematics and Science. Contextual questionnaires were administered to learners, class teacher and principals of the sampled schools which served as rich information to describe the context of schooling.

Outcome variable
Learners were asked to respond to nine statements asking how often they experienced different types of bullying in schools. The set of questions were based on a Likert scale which ranged from ‘at least once a week’ (Code 1) to ‘never’ which was assigned a code four. Learners were asked how often they were made fun of, if they were intentionally excluded from games, whether rumours were spread about them, something that they owned was stolen, whether they were hit or hurt, forced to do things they were not comfortable with, etc. Each of these was reverse coded so that a higher value would indicate being bullied more often. When combined, these statements provided a Cronbach’s Alpha of 0.78, which is an indication that the scale is reliable.

Using IEA-designed software for sampling; TIMSS uses a stratified two-stage random sampling design in which a sample of schools is selected at the first stage. At the second stage an intact Grade Nine class is randomly selected across Grade Nine classes in each of the sampled schools. Intact classes are selected because TIMSS pays close attention to issues of classroom practices and experiences. The realised sample consisted of 292 schools and approximately 12,514 learners were selected and stratified by language of instruction (English, Afrikaans and dual medium schools), province, and type of school (public or independent).

Variables included
The variables included in the analysis were selected as either controls, or were selected from scales created by the International Association for the Evaluation of Educational Achievement (IEA); which were included in the analysis as continuous variables (see Table 1). Each of the IEA scales were composed of a number of statements that the principals and learners were asked to respond to, and which, when combined, measured a single underlying construct. These scales were created using Item Response Theory (IRT) scaling methods. Details on how the scales were developed is provided in the Methods and Procedures report (Martin, Mullis & Hooper, 2016). The following section mentions the scales considered as part of the analysis, as well as the statements included in each scale.
Independent variables
Variables included as controls
The variable extracted from the learner questionnaire was learner gender – a dichotomous variable – with boys coded as 1 and girls coded as zero.

Home Socio-Economic Status (SES) was a scale comprised of various resources in the home. SES was a continuous variable standardised to a mean of zero and a standard deviation of one.

Age was also considered, and a dichotomy was created that compared age appropriate learners to all other learners.

Learner school climate variables
Learners were also asked to respond to statements pertaining to their school environment. Using learners’ responses to these statements three scales were created and included in the analysis; the first focused on learner engagement in Mathematics lessons, and included 10 statements that asked learners to what extent they were in agreement with the statement regarding their Mathematics lessons. The responses ranged from a code of one (agree a lot) to a code of four (disagree a lot). The variables included in this scale were reversed coded, so that high values indicate high levels of engagement. The set of statements enquires about teacher classroom practices from the learners’ perspective and the construct was reliable with a Cronbach’s Alpha of 0.86. Some of the statements included were whether the learner considers the teacher easy to understand, feels that the teacher always ensure that the learners are academic stimulated, the teacher is innovative when assisting learners grasp what is being taught, the teachers listens to what the learner has to say, etc.

The second scale was learners’ sense of belonging, which included seven statements, where learners were asked about the extent to which they agreed or disagreed with the statements. The response options ranged from “Agree a lot” coded as 4 to “Disagree a lot” coded as 1. The scale was reliable with a Cronbach’s Alpha of 0.72. The statements learners were asked to respond to focused on how they felt about the school they attend, its environment and relationships with other learners and teachers.

The third scale looked at learner confidence in learning Mathematics. It included nine statements and asked students the extent to which they agreed or disagreed with statements like how well they do in Mathematics, whether Mathematics is more difficult for the learner than other learners in their class, how comfortable they are learning Mathematics, etc. The scale was reliable with a Cronbach’s Alpha of 0.78

Principal school climate variables
The fourth scale included focused on discipline problems that might occur in schools. A high value indicated a school that had very little or no discipline problems and a low value indicated a school with serious problems with discipline. The scale included statements like late arrival at school, absenteeism, dishonesty, vulgarity and theft, verbal abuse, physical injury, etc. The scale was reliable with a Cronbach’s Alpha of 0.91.

The emphasis that schools place on academic success was added to the model and principals were asked to respond to 13 statements, which ranged from low emphasis to very high emphasis. The scale was reliable with a Cronbach’s Alpha of 0.89 and included statements that focussed teacher knowledge of the curricular, successful implementation of the curricular, expectation of academic achievement, parental involvement in the academics of their children, learners desire to do well and reach academic goals, etc.

School socio-economic status
In order for the DBE to adequately allocate financial resources to public schools in South Africa, provinces were required to categorise schools into five quintiles, which is defined as the poverty ranking of the school. The poverty ranking that schools received was dependent on the poverty level of the community surrounding the school. Quintile one was assigned to schools that were poor and quintile five referred to wealthier schools.

The department refers to the first three quintiles as no-fee paying schools since parents whose children attend these schools are exempt from paying school fees. Schools categorised as quintile four and five are referred to as fee-paying schools. Learners who attend these schools are expected to pay school fees.

For the current analysis these categorisations will serve as proxies for SES of public schools. No-fee will be referred to as ‘low SES public schools’ and fee-paying was referred to as ‘high SES public schools.’ An additional category was included in the analysis to refer to the independent schools’ sector in South Africa which are schools recognised by the DBE but is managed by an independent body.

Data Analysis
To test the association between school climate and students being bullied, a multiple regression analysis was performed using SPSS version 24 and IEA International Database (IDB) Analyzer (version 4.0). IDB Analyser was designed by the IEA to assist with the analysis of large-scale survey data that follows a complex sampling design and employs plausible value techniques when dealing with student achievement the multiple regression assumptions were tested and met. These assumptions included: testing for multicollinearity between independent variables, uncorrelated residuals and that the residuals are normally distributed.
Listwise deletion was used to handle missing data and hence the analysis included 11,785 of the 12,514 learners.

**Results**

Table 2 presents the results of the multiple regression analysis done on the association between school factors and bullying. The selected learner and school factors explained 13.5% of the variance in the bullying scale.

The column “Standardised Coefficients (t-value)” provides the t-statistics, which refers to the strength of the relationship between the dependent and independent variables. A higher value indicates a stronger association. In order of highest to lowest value, the results show that learner sense of belonging (t = -11.36) has the strongest relationship, followed by: average Mathematics achievement (t = -9.08); learner confidence (t = -5.14); learner engagement (t = -4.95); the type of school that learners attend (t (high SES public schools) = -4.47; t (independent schools) = -3.09); and finally, the emphasis placed on academic success (t = -3.02).

The results show that two of the three control variables considered were significantly associated with learners who are bullied more often. Home SES was not significantly associated with bullying, however, learners who are age appropriate for the grade are bullied less often (β = -0.272, p < 0.01). A significant gender difference with respect to bullying was observed, with boys being bullied more often than girls (β = -0.272, p < 0.01).

**High SES Public Schools**

Learners are less likely to be bullied if they feel that they belong at the school. The results show that higher levels of belonging are associated with a lower incidence of bullying in schools (β = -0.27, p < 0.01).

A strong association is observed with average Mathematics performance and bullying in schools (β = -0.01, p < 0.01): learners who are bullied often obtain a significantly lower score than that of learners who are bullied less often or never bullied.

Learners who are confident (β = -0.11, p < 0.01), and who are always engaged in their lessons (β = -0.12, p < 0.01), are less likely to be bullied than learners who are neither confident nor engaged in their lessons.

The scale pertaining to the extent to which discipline is a problem in schools is not significantly associated with the occurrence of bullying in schools.

The emphasis that a school places on academic success is also important, as clear academic expectations are set that learners need to achieve. The results show that schools that place a higher emphasis on academic success have a lower occurrence of bullying in schools (β = -0.10, p < 0.01).

The type of school that learners attend also makes a difference, with learners who attend high SES public schools (β = -0.71, p < 0.01) and independent (β = -0.82, p < 0.01) schools being bullied less often than learners who attend low SES public schools.

**Discussion**

Schools are an important socialisation force and student-teacher relationships play an important role in affecting both academic and social outcomes (Konishi, Hymel, Zumbo & Li, 2010). The effect of bullying on student peer relationships is inversely associated with school performance, and positively associated with greater school liking, and greater self-direction (Konishi et al., 2010).

The results that will be discussed in this section points to initiatives that need to be established in both the developed and emerging economies to curb the spate of bullying occurring within schools. The aim of this study was to explore the extent to which school level factors explain the prevalence of bullying at schools in South Africa.

The results show that a strong relationship exists between learner sense of belonging and the incidence of bullying at schools. This is in line with findings by Bacchini, Esposito and Affuso (2009) and Waasdorp et al. (2011). Learners who are faced with incidents of bullying often feel like they do not belong at the school and have trouble engaging socially (Thompson, 2018; Underwood & Ehrenreich, 2014). Schools need to make a concerted effort to create an environment where learners and parents feel welcome, and ensure that policies focused on safety and discipline in schools are strongly adhered to.

The adverse association between learner achievement and incidence of bullying at schools has been researched extensively and the results found by many authors (Juvenen, Wang & Espinoza, 2011; Lillis, 2011) concur with the results found in the current paper. Learners who are bullied on a regular basis obtain scores of up to 68 points lower (on average) than learners who are never bullied or almost never bullied (Reddy et al., 2016).

Regarding analysis of learner engagement and confidence, we found results similar to those found by Finn (1989), Goodenow and Grady (1993) and Ma (2003), namely that learners who are more engaged and have confidence in learning Mathematics are less likely to experience bullying. This is also true in terms of learners’ sense of belonging.

*Note. ns = Not statistically significant.*
The SES of the school that a learner attends is strongly associated with the prevalence of bullying at schools. The results show that learners who attend high SES public schools or independent schools experience lower incidences of bullying than learners at low SES schools. This finding concurs with Zaze et al. (2016), who found that the incidence of bullying at public school was higher than at independent schools.

The school is a reflection of the community surrounding it, and that low SES communities are usually higher crime and violence rates. Interventions focused on school climate need to be rolled out in schools with a strong emphasis on creating bully free environments like these, often also referred to as strong links have been found between bullying at their school and school-based violence.

Study Limitations
One of the limitations of the study is that it was based solely on self-reported from the learner and the principal contextual questionnaires. The analysis provided some interesting findings that need to be investigated further possibly with an in depth qualitative study. The analysis was limited to the definitions and measures of bullying and school climate included in the TIMSS study. The factors of both bullying and school climate are very broad and it could be possible that the TIMSS measures are not best suited for the South African context. This was however the only data the authors had at their disposal.

Conclusion
In order for learners to have a successful academic career, it is important that they are exposed to environments where emphasis is placed on academic success, where they feel safe, feel like they belong, and are constantly engaged in the classroom. It is in environments like these, often also referred to as schools with a healthy climate, that constructive teaching and learning takes place and issues of bullying are low or non-existent. It is clear from the results that a school’s access to resources also play a role since learners are more likely to be exposed to incidences of bullying in low SES schools than learners who attend higher SES schools. A school is a reflection of the community surrounding the school and strong links have been found between community SES and violent behaviours, in that low SES communities are synonymous with high crime rates. Interventions focused on school climate need to be rolled out in schools with a strong emphasis on creating bully free environments for all learners. However, broader community based changes are important as well so that learners feel safe not just at school, but also in the communities in which they live.
