Enhancing climate governance through indigenous knowledge: Case in sustainability science

The current tempo of climate change strategies puts the notion of sustainability in question. In this philosophy, mitigation and adaptation strategies ought to be appropriate to the sectors and communities that are targeted. There is a growing realisation that the effectiveness of both strategies hinges on climate governance, which also informs their sustainability. The application of the climate governance concept by the technocratic divide (policymakers and climate practitioners) to communities facing climate change impacts, however, is still a poorly developed field, despite extensive treatment by academia. By drawing heavily from conceptual and analytical review of scholarship on the utility of indigenous knowledge (IK) in climate science, these authors argue that IK can be deployed in the practice of climate governance. It reveals that the merits of such a deployment lie in the understanding that the tenets of IK and climate governance overlap and are complementary. This is exhibited by examining the conceptual, empirical and sustainability strands of the governance-IK nexus. In the milieu of climate change problems, it is argued that the basic elements of climate governance, where actions are informed by the principles of decentralisation and autonomy; accountability and transparency; responsiveness and flexibility; and participation and inclusion, can be pragmatic particularly to communities who have been religiously observing changes in their environment. Therefore, it becomes necessary to invigorate the participation of communities, with their IK, in designing climate change interventions, which in this view can be a means to attain the objectives of climate governance.

Introduction

The Intergovernmental Panel on Climate Change (IPCC), a brainchild of the United Nations Environmental Programme (UNEP) and the World Meteorological Organisation (WMO) established to give the most comprehensive overview and fact base of climate science, recognises climate governance and indigenous knowledge (IK) in the ongoing climate change discourse. Both concepts, however, are treated in fragmentation. Despite this segmentation, there is a growing appetite by both climate governance community and indigenous knowledge researchers to examine the usefulness of the concepts in climate interventions. In climate regimes, it can be argued that climate governance has dominated climate discussions more than IK.1-3 This dominance continues to grow against a backdrop where the intergovernmental policy arena faces substantial impasse on what constitutes climate governance. The intricacy of the stalemate arises from a tradition characterised by a disparate magnitude of contribution existing between the global North, largely blamed for greenhouse gas (GHG) emissions, and the global South, paradoxically experiencing extreme climatic events. Indigenous climate knowledge, following at a distance behind climate governance, continues to occupy space in climate literature, albeit with limited realisation of the relationship between these concepts. It is therefore essential to advance discourse by examining the relationship between climate governance and IK. In this paper, we argue that IK has potential to transform the technocratic-community engagement front in the current discussions where climate science and policy regimes are increasingly being interrogated for their sustainability.

Conscious of the conceptual and definitional flaws, and the intricacies characterising climate discourse, we proceed by treating climate governance as a concept embracing inclusivity in designing mitigation and adaptation strategies by all climate stakeholders, including indigenous communities affected by climate change. Adaptation governance, a concept that has dominated climate discussions to date, centres, for example, on participation, equality and justice in decision-making about interventions to contain climatic events. Meadowcroft4 says that, at country level, this requires adequate knowledge about anticipated climate effects and planning to tackle anticipated impacts on human activity. On the other hand, mitigation governance calls for an understanding of emission sources, cost-effective containment potentials, and policy approaches.1,2

In a related treatment, IK is a knowledge form defined by Orlove et al.4 as place-based and rooted in local cultures that are mostly associated with long-settled communities who have strong ties to their natural environments. The concept is now increasingly acknowledged by the IPCC as evidenced by distinct sections covering IK in its latest reports.5,7 The disaster management community is also drawing heavily from the experiences of indigenous people with the view of making impacting risk and disaster management interventions.6,12

Evidence of IK’s usefulness in climate science ranges from enhancing understanding of climate impacts,13-15 particularly at local scale where scientifically advanced models tend to give a coarse-grained focus,16 to informing successful mitigation and adaptation interventions13,17-19 whose success could be credited on meaningful community participation in identifying appropriate climate projects.15,20-22 A demonstration of the climate governance-IK linkages is given in this paper. This is exclusively done through reviewing literature on climate governance and indigenous knowledge across the world.

The overriding theme in this analysis is the interrogation of the notion of sustainability science. The genesis of this philosophy is traced from the United Nations Educational, Scientific and Cultural Organisation (UNESCO) Declaration on Science and the Science Agenda Framework held in Budapest, Hungary in 1999.23 Earlier,
sustainability as a concept gathered impetus following the 1992 World Earth Summit on Environment and Development held in Rio de Janeiro, Brazil26 but was preceded by the 1987 Brundtland Report27 that specified a framework for sustainable development articulation. Within this view, in order for scientific interventions to be sustainable, a platform that incorporates the active involvement of citizens who should be served by the science ought to exist. In the context of climate governance, therefore, climate science should be seen by local people as a shared asset that helps them to seek practical solutions to the problems and opportunities brought by change and variability in the climate system. The paper implores that the praxis of climate governance at local level is potentially realisable when indigenous communities, with their invaluable reservoirs of climate change knowledge, actively participate in climate regimes. Four cases relevant in climate mitigation and adaptation are thus drawn here:

- The envisaged benefits of local participation in programmes like that on Reducing Emissions from Deforestation and Forest Degradation (REDD+), a mechanism whose thrust is to enable communities in developing countries to benefit from climate funds if they actively partner in forest projects that enhance carbon sinks
- Land Use, Land-Use Changes and Forestry (LULUCF), intended for atmospheric carbon stabilisation through regulated activities in local land-use planning and management
- Community-based adaptation (CBA), a bottom-up framework for making effective adaptation through the central role of local people
- Ecosystem-based adaptation (EBA), an approach that serves both objectives of climate proofing and emission reduction through harnessing ecosystem services coupled with wise management of the same.

The benefits of a climate governance-indigenous knowledge nexus are discussed here from conceptual significance, empirical evidence to sustainable development. But first, it is crucial to trace the major developments on governance around climate change so as to contextualise the discussion.

Nature of climate governance and problems of articulation

There is phenomenal growth in literature that examines the concept of climate governance. However, this has not resolved the current impasse in the application of the concept in the global policy arena that has been in existence for the past two decades. Biermann and Boas28 argue that the difficulties emerge from the intricacies of the phenomenon itself, where climate change is seen as a problematique both in causation and consequences, where the industrialised societies, largely to blame for the anthropogenic forcing of climate destabilisation, should have a moral responsibility to contain its devastating impacts. Most authorities agree that complexities in conceptualising climate governance mirror both the multi-layered spatial scale and multi-sectoral levels of application.29-32

Van Asselt31 for example, views this as a fragmentation of climate governance. Bulkeley and Moser32 agree with Andonova et al.28 that climate governance needs to be decentralised beyond multilateral agreements, and diffused across many actors in society. Backstrand and Loubrand30 pose that the concept has to be understood from competing discourses of green governmentality, ecological modernisation and civic environmentalism, where \'local\' is pitted against global, North vs South, public vs private, decentralisation vs centralisation, and economic efficiency vs environmental integrity. Other scholars, like Pattberg and Strupczewski and Sarath,33 adopt the term global governance, arguing that the challenges of climate change are global in dimension and cannot be addressed by national or regional interventions alone. Clearly, it can be inferred from these authorities that climate governance is a multifaceted term with a varied scale of application.

At a higher level, governance of climate change is predominantly seen in the 1992 United Nations Framework Convention on Climate Change (UNFCCC) and the 1997 Kyoto Protocol. The UNFCCC is designed to stabilise GHG concentrations to levels that would not interfere with the earth’s climate system, while in addition to sharing the objectives of the Convention, the Kyoto Protocol commits industrialised countries to stabilise their GHG emissions. Ashton and Wang34 are of the view that the two regimes reflect a general calculus of equity through the principle of common but differentiated responsibilities. Under this framework, attention can be given to poor and vulnerable societies to acquire technology and funds to adapt to climate change. However, the intergovernmental policy landscape still faces challenges in articulating the idiosyncrasies of climate impacts permeating diverse sectors that are not clearly specified in the multilateral climate agreements. Van Asselt35 argues that the international environmental law in place has not been able to comprehensively deal with the issue of global climate governance. One of the areas not clarified by these regimes is the phenomenal increase in the population of climate refugees as noted by Biermann and Boas28 and Martin25.

At the regional level, for example, the European Union (EU) and Southern African Development Community (SADC), climate governance can be effected through appropriate regional environmental policies and protocols. Oberthür36 is of the view that the limitations of the current global climate institutional architecture can be reinforced through strengthening regional climate policies, such as that of the EU. In Africa, for example, these regimes have been characterised by a fragmentation of responses, which has not done justice to the demands set by climate governance.26

Nationally, climate governance is tackled in the form of climate policies and institutions. In most countries, however, the policy domain is marked by a patchwork of public and private institutions that differ in their mandates and interests, with potential to cause conflicts that are likely to stymie governance issues.26 Meadowcroft’s37 paper looks at national level climate governance, which can be influenced by promoting coalitions for change, minimising antagonistic forces, establishing centres of economic efficiency, creating robust institutions, adjusting national environmental legislations, and transforming citizen behaviour. He cites the problem of institutional inertia, where perceptions about adverse consequences of mitigation policies in combination with scientific uncertainty tend to block progress towards the attainment of global climate governance.

In order to address some of these problems, United Nations Development Programme/ United Nations Capital Development Fund/ United Nations Environment Programme (UNDP/UNCDF/UNEP)38 identifies 5 entry points for enhancing the way in which national or local governments can interface with climate change:

1. National climate change and sub-national governance policies should involve clear links between national policies and decentralisation/ sub-national policies, especially in developing countries where such linkages are best described as weak or non-existent
2. Improving local understanding of climate change issues; that is, knowledge of what climate change means to local governments in concrete and tangible terms, such as information on nature and risks they face
3. Financing arrangements for climate change; including corruption proofing, where there is room for information transparency and oversight on resource use by community stakeholders
4. Operationalising local democracy for vulnerable groups such as involving indigenous peoples in climate change decision-making processes and adaptation strategies, which would include the use of indigenous knowledge and innovations
5. Addressing the capacity question, where capacity assessment of institutions, organisations and individuals is interrogated

Because these problems of articulation at differentiated spatial and sectoral levels, the emerging situation is that climate governance remains a rhetorical commitment, particularly when viewed from the perspectives of poor and vulnerable communities relying on climate-sensitive liveli-
hoods. Despite increasing global certainty about anthropogenic forcing of climate change and the challenges it poses on humanity noted by the IPCC’s report, Oberthür’s remarks resonate with Pattberg and Strümpfel’s earlier observation that the policy architecture in place is incapable of effectively addressing climate change. Here we propose a configuration that links climate governance and IK in order to operationalise climate governance, with the intention of offering directions for building resilient sustainable communities in many parts of the world experiencing climatic events.

Climate governance-IK linkage: A conceptual necessity

Governance refers to the ways in which scale level decision-making takes place. It is called ‘good governance’ when it reflects scrutinisation and oversight by citizens, openness and transparency and participation. The IPCC views governance in climate change as a more inclusive approach that recognises the various levels of government (global, international, regional, national, local) and the responsibilities of the private sector, non-governmental actors and the civil society. The problem of conceptualisation has been widely reported by other scholars such as Chirisa and Chanza, Bulkeley and Moser, Pattberg and Strümpfel, Okeke and Bulkeley, and Macey. Even suggests a redesign of the climate governance framework from scratch, while Bulkeley and Moser recommend a shift from conceptual necessity to empirical reality. Chirisa and Chanza adopt a local governance perspective in order to demystify the institutional strictures, dispel corrupt tendencies and empower citizens for participatory democracy.

Apparently, most scholarly work is silent regarding examining the role of indigenous knowledge in climate governance. For example, scholars like Orlove, Nyong et al., Berkés, Mawere, and Mawere et al. who have written extensively on IK applications in climate change, have not embraced this concept. Espousing the spatial dimensions of applicability featuring prominently in many scholarly work and policy regimes, a re-examination of climate governance would point towards climate governance-indigenous knowledge connectedness. This linkage is argued here as a conceptual necessity for premising climate governance.

IK as a concept, defines knowledge that is location specific, acquired in situ, through progressive study of the community’s interaction with the environment, and orally transferred both within and between generations. Sees IK as useful in establishing a moral virtuous society whose usage helps African communities to realise a sense of responsibility in environmental resource exploitation, thus ensuring food security in the event of environmental shocks like drought. This knowledge strengthens the education of the African population, which is a necessary foundation for sustainable development. Some key issues related to governance can be inferred from this conceptualisation. Firstly, the knowledge is understood collectively to include community skills, technologies and practices that give the community collective understanding and responsibility to sustainably utilise the environment. Secondly, in both theory and praxis, the concept is holistic, empowering and participatory. As can be seen in Figure 1, IK elements are a function of climate governance. Here the major elements characterising climate governance are also found in the utilisation of IK. For instance, the knowledge form is decentralised at grassroots level structures in an autonomous arrangement where there is no exclusion in accessing the knowledge. Whenever a response to climatic events such as floods and drought is called for, users of IK are flexible to actively choose available coping and adaptive options for climate proofing. Although not clearly referring to the concept of climate governance in their arguments, Gwimbi, Mawere et al. and Chanza write about the significance of IK in mitigating the negative effects of climate change such as floods, violent storms, dry spells and drought.

Climate governance-IK linkage: An empirical reality

The climate change community cites mitigation and adaptation as central themes governing climate interventions. Mitigation, in climate science deployment, is a dual-faceted concept: firstly, as a human intervention to reduce sources or enhance sinks of GHGs; and secondly, as the moderation of potential adverse impacts of climate risks and disasters through actions that reduce hazard, exposure and vulnerability. In order for local mitigation programmes to be effective, they need the support of key stakeholders that include local citizens where activities are implemented. Two interventions used by the IPCC and the UNFCCC worth noting here are REDD+ and LULUCF.

REDD+ is a carbon compensation programme that covers the role of conservation, sustainable management of forests and enhancement of forest carbon stocks in developing countries. In the planning and implementation process of the programme, the full and effective participation of indigenous people who use their IK to manage forestry resources can be realised. Through traditional resource management regimes, indigenous people can translate climate governance into practice. For example, the effectiveness of REDD+ projects in Brazil, Indonesia, Kenya, Mexico, Peru and Tanzania is attributed to participatory planning involving local citizens whose knowledge is crucial in the technical analysis to address the drivers of deforestation and forest degradation, as well as barriers to sustainable management.

The fifth assessment report (AR5) of the IPCC reports that GHG emissions from agriculture comprised about 12% of manufactured pollutants in 2010. This makes LULUCF a critical area for mitigation strategies. Furthermore, the Kyoto Protocol identifies changes in carbon stocks and GHG emissions by sources and removals by sinks related to direct anthropogenic land-use change and forestry activities. In order to operationalise this strategy at local level, customary laws and practices governing land-use, land and forestry management activities in rural communities of most African societies, for example, can be drawn upon. In Zimbabwe, for instance, Mahamed-Katerer concludes that land-use practices are interwoven with cultural beliefs under the administration of local traditional leaders in a philosophy she calls ‘environment-spiritual connection’. Within this belief system, she cites two laws that guide sustainable land management. The first is a collection of rules that link abuse of resources to spiritual sanctions. Alongside this, there are also spiritual rules that restrict use and condemn unsustainable exploitation.
In a similar case, Turner and Clifton in their study targeting indigenous citizens of Hartley Bay in British Columbia, Canada, observe that the motive behind sustainable land and forestry resource utilisation is the strong indigenous belief that the resources belong to ancestry and the spirits. As such, the locals have a moral and spiritual obligation not to violate the environment. This means issues of governance are properly understood and practised at grassroots levels that shape human-environment interactions.

In climate literature, adaptation is treated as a response interventions to some climate stimuli so as to minimise harm or enhance the benefits brought about by climatic conditions or events. Strategies to contain climatic events are usually practical at local or project level involving interactions with the people. In this way, the participation of indigenous people using their knowledge, skills and experiences drawn from many years of coping and adapting to changing and variable environments deserve emphasis.

One of the predominantly preferred strategies by the climate change scholars and practitioners is community-based adaptation (CBA). CBA is viewed as a community-centric approach whereby the locals are positioned as the main stakeholders in the implementation of coping and adaptive interventions. The intention is to build adaptive capacity and enhance community resilience against the disturbances potentiated by destabilisation in the climate system. In application, it can be seen that this strategy embraces a bottom-up approach where indigenous people are given respect and space to select from a toolbox of their own adaptation options. Kirkland emphasises that CBA projects are more effective if they actively solicit the input and participation of local people, which from the viewpoint of Enso is governance for community-based adaptation.

In a study to understand the value of IK in climate adaptation in the African Sahel, Nyong et al. mention 5 reasons meriting giving attention to local knowledge in order to guarantee successful adaptation. These are IK:

- is rich in cultural context
- is an appropriate and sophisticated knowledge form
- increases community buy-in
- promotes equity, efficiency and environmental integrity
- leads to increased communication and understanding

Experiences by Practical Action, working with indigenous rural communities in Bangladesh, Kenya, Peru and Zimbabwe show that for adaptation governance to be realisable it ought to be “…understood as a process, through which communities gain access to skills, resources and information so that they can continuously shape their lives and livelihoods as the environment changes around them.”

Another key strategy capable of operationalising the climate governance-IK linkage to advance both the goals of mitigation and adaptation governance, is that of ecosystem-based adaptation (EBA). Defined by Munang et al., EBA “is the use of natural capital by people to adapt to climate change impacts, which can also have multiple co-benefits for mitigation, protection of livelihoods and poverty alleviation.” In other words, the concept provides multiple benefits for society and the environment as it contributes to reducing vulnerability and increasing resilience to both climate and non-climate risks. Worth noting is that the main activities of EBA, listed by the UNFCCC as vulnerability assessment, capacity building, designing policy measures and implementation, can involve local people leveraging their IK to ensure adequate climate proofing and emission reduction. The Sweden case involving ecosystem-based measures by the local farmers is given as an example (see Box 1).

### Box 1: Farmers network using ecosystem-based measures to cope with uncertain climatic conditions

Adjusting management practices, including adopting traditional farming techniques, can help to increase resilience and reduce vulnerability to the effects of climate change. The east-central area of Sweden presents difficult climatic conditions for small-scale farmers who experience long winters and frequent periods of drought. This climatic uncertainty, combined with threats from pests and disease, presents challenges for sustaining livelihoods, with climate change expected to exacerbate these conditions. To build resilience, farmers in the Roslagen region began incorporating a range of ecosystem-based practices. Measures included diversification of crops in time and space to reduce the risk of crop failure, using multiple crop varieties to increase genetic diversity and pest resistance, incorporating crop rotation to revitalise soils and prevent pest infestations without reliance on chemical fertilisers and pesticides, and planting shade trees and cover crops to enhance seedling survival to cope with drought. In addition, by establishing an informal local network, the farmers were able to share best practice and local ecological knowledge. The ecosystem-based measures led to the farmers producing high-quality and organic products, whilst increasing their resilience to climate variability and change. Biodiversity and economic security has also been enhanced.

It should be noted here that focussing on IK does not guarantee the project will be equitable, just and successful, as expected in climate governance. Sri states that given the appropriate conditions, local knowledge is capable of making interventions more effective. One of the factors that guarantees successful mitigation and adaptation for local based projects is the existence of social capital as defined by Woolcock and Narayan as the standards and networks that drive people toward collective responsibility and action. Under this concept, the role of social networks, community linkages and institutional structures can be exploited to enhance the objectives of climate governance or to build community resilience against the devastating impacts of climate change.

### Climate governance-IK linkage: A drive towards sustainability

In the preceding sections, we have argued that the realisation of social, economic and environmental sustainability can be enhanced by mitigation and adaptation options that are appropriately crafted through issues of participation, consultation, inclusivity, efficiency, accountability and decentralisation. The IPCC’s emphasis that ‘sustainability in the context of climate change is addressing the underlying causes of vulnerability, including the structural inequalities that create and sustain poverty and constrain access to resource’ is worth noting. In other words, climate governance should be the means to sustainability. Backstrand and Loubrand suggest that the composition of future global climate governance should address elements of fairness, burden-sharing, poverty alleviation, participatory democracy and sustainable development. The Climate Action Network gives guidelines that can be followed for adaptation governance to be sustainable. The principles for adaptation governance are summarised as:

- Prioritise the adaptation needs of, and ensure that resources reach, the most vulnerable, including marginalised groups, women and children, indigenous peoples, local communities and those disproportionately impacted, as well as vulnerable ecosystems, through enhancing adaptive capacity and reducing vulnerability.
- Recognise that responses will have to be based on local assessment of risks, needs and circumstances and be relevant to local people and communities.
- Maximise national, sub national and community level ownership over adaptation planning and implementation processes, and disbursement of adaptation finance, in order to enable and encourage participatory local level planning and implementation.
- Plan and implement adaptation actions in a transparent and well-documented way that is open to public scrutiny and discourse. Ensure...
the representation of key stakeholders, especially representatives of vulnerable communities, marginalised groups, women, and indigenous peoples at every stage of the process as appropriate – including in the governance and disbursement of adaptation finance, planning, implementation, monitoring and reporting.

- Adopt a process-driven learning-by-doing approach on adaptation planning and implementation, respecting the Precautionary Principle while recognising the urgency to adapt in the absence of complete information and the need to develop and implement flexible plans and programmes that can be updated on the basis of new information and learning.

As the global community drifts towards the post 2015 sustainable development goals (SDGs) marking a paradigmatic shift from the millennium development goals (MDGs), there is need to retrospectively centralise discourse on the sustainability of climate interventions as climate change will remain a cornerstone of the SDGs. The issue of translating climate governance rhetoric into practice should be the central theme of such a transformation. It should be learnt here that local community knowledge, skills and experiences are key in shaping sustainable climate interventions.

**Conclusion**

In the milieu of climate governance rhetoric characterising the climate regime terrain, the potential role that IK can play in transforming theory into practice deserves attention. The view advanced in this debate is that of taking governance issues to the people who are facing climate impacts. It is hoped that the first point of entry for meaningful climate mitigation and adaptation is at the local level where knowledge and experiences of those witnessing the climate phenomena can be harnessed. The effectiveness of REDD+ and LULUCF projects, which are being considered as driving climate stabilisation agendas in many parts of the world, should not be devoid of elements of local governance reflecting local input through IK. Similarly, if adaptation is to build community resilience and adaptive capacity, adaptation governance informed by IK and experiences of locals cannot be ignored. Prioritising local climate governance would translate into local sustainable development which could lead to potential ramifications in higher levels and towards global sustainability. Therefore, it serves to mention that climate governance dialogue should be supported starting at grassroots where indigenous people, with their banks of IK, should characterise the policy discourse for sustainability.
