Summary
We report on a primary laparoscopically assisted anorectal pull-through (LAARP) performed in a neonate with pure oesophageal atresia and imperforate anus with recto-bulbo-urethral fistula, representing a unique case for the LAARP approach owing to the undistended nature of the bowel and sterile meconium. Further evaluation of the applicability of LAARP in the management of infants with anorectal malformations is needed, but in this case it held major advantages for the patient. A laparoscopically assisted gastrostomy was facilitated during the same procedure, while avoidance of a colostomy and its associated complications also facilitated preservation of the left colon for subsequent use in oesophageal replacement. Long-term outcome remains to be assessed.

Case presentation
A male infant was born with a high imperforate anus and pure oesophageal atresia. A LAARP and a gastrostomy were performed on the second post-natal day. Primary oesophageal repair at 6 weeks failed, and the infant was discharged home to continue anal dilations. Stooling was regular with no constipation. Oesophageal substitution is planned after 10 months of age.

Surgical technique of neonatal LAARP
The rectum was identified and dissected down to the level of the proximal bulbo-urethral fistula. The fistula was transsected as close as possible to the urethra. Perineal electrostimulation identified the centre of the anal sphincter, and an oval disc of skin was excised within this area. Visualising the midline of the puborectalis sling from above, we then dissected bluntly into the peritoneal cavity, after which a 5 mm port was inserted and used to pull the rectum through. A standard anoplasty was then fashioned and a urethral catheter left for 5 days.

Discussion
Concomitant ARMs are found in about 10 - 15% of patients with oesophageal atresia (OA), although the incidence may be as high as 23% in patients with OA without tracheo-oesophageal fistulae. OA without fistula represents about 7% of OA, and is therefore likely to be present in about 0.8% of ARM patients, based on a 12% incidence of OA occurring with ARM.

Primary anorectoplasty is routinely performed in low ARMs. Definitive repair of ARMs with recto-urethral fistulae in the newborn period is not recommended, owing to increased risk of injury to genito-urinary structures from ‘blind’ exploration without the anatomical information gained from a colostogram, and the increased risk of infection and wound dehiscence without faecal diversion. Pena’s posterior sagittal anorectoplasty (PSARP) is the gold standard in the management of ARMs with recto-urethral fistulae, replacing the Kiesewetter-Rehbein pull-through. In 2000, Georgeson introduced a
laparoscopically assisted approach.34 While the advantage of laparoscopy in bladder-neck and prostatic-urethral fistulae is clear,27-28 as laparotomy would otherwise be required, only a few small series report on laparoscopy in the management of other 'high/intermediate' malformations with recto-urethral fistulae.35 One possible limitation of the laparoscopic approach is the imprecise angulation of the ano-rectal canal, which is easily positioned under direct vision in the open Pena dissection, although possibly at the expense of increased damage to nerves and muscle fibres. Various adjunctive techniques such as ultrasound guidance36 and magnetic resonance imaging (MRI)37 have been used to improve this approach. Other concerns are inadequate excision of the recto-urethral fistula,38 with creation of a urethral diverticulum, although evidence for this actually limited.27,28 As laparotomy would otherwise be required, only a few laparoscopy in bladder-neck and prostatic-urethral fistulae is 'high/intermediate' malformations with recto-urethral fistulae. Small series report on laparoscopy in the management of other oesophageal atresia caused morbidity in this patient, these do not detract from the initial success of the LAARP, which held major advantages for this patient because of the avoidance of colostomy and the preservation of the left colon for use in future oesophageal replacement. Long-term functional outcome will need to be assessed when the child is older.
