

Reflections for global public health research and evidence-based medicine during the COVID-19 pandemic

Healthcare professionals are often overburdened, with limited time to examine all current, best available evidence to inform their practice and clinical decision-making. This has been very much the case during the COVID-19 pandemic, with healthcare professionals at the frontline facing physical exhaustion, mental health challenges associated with stigma, limited family time, and the passing of those seeking healthcare.^[1] In addition to some of the psychosocial factors impacting on healthcare professionals, the surge in the available evidence during the COVID-19 pandemic made clinical decision-making cumbersome, as evidence-based medicine attempted to address clinical decision-making through the best available evidence together with clinical expertise and patient values.^[2]

As the World Health Organization (WHO) declared a global public health emergency, the world saw an increase in the number of COVID-19 cases. Researchers and academics rapidly responded to this public health emergency through the generation of knowledge that aimed to be both relevant and timeous to address the needs of the pandemic and halt the number of infections for those at great risk. The rapid response meant that while researchers aimed to inform the public and the scientific community about advances in science, methodological and ethical dilemmas emerged as part of evidence-based decision-making. Cutting corners and producing evidence rapidly often meant that researchers and academics needed thoughtful reflection about whether they are guilty of exploiting the COVID-19 pandemic for academic progression while losing methodological and ethical integrity. In April 2020, the WHO database reported 5 362 COVID-19-related studies and numerous online COVID-19 collections (such as the Living Overview of Evidence platform and the Living Systematic Map of Evidence, to name but two).^[3] Would the adaptations to evidence-based medicine that the pandemic brought about change how evidence generation and synthesis is conducted in the future? Yes, this has already occurred, and will most certainly continue to do so. An example would be the move away from the traditional qualitative evidence generation, which often requires in-depth, in-person interaction, towards the more virtual space through online data collection methodological approaches to still yield data that are rich and detailed. Simultaneously, it could also suggest that this is the shift from traditional research methods and approaches to ones that are changing with the times – in light of the fourth industrial revolution and the current pandemic.

Yet, while there are many changes and adaptations to our traditional views of evidence-based medicine, generation and synthesis, we need to make sure that as researchers and academics we do not lose our methodological and ethical integrity. Some reflections that researchers and academics might need to consider to avoid jeopardising the methodological and ethical integrity of scientific contributions are set out in Fig. 1.

All attempts at global public health research and evidence-based medicine should take place while the researcher reflects on how she/he can ensure that the knowledge generated and shared can be relevant to help clinicians and the general public, locally. The language that is used in the dissemination and knowledge translation of evidence that emerges from research during the COVID-19 pandemic should also consider the availability of evidence in languages other than English, both languages widely spoken internationally (such as the inclusion

REFLECTIONS FOR GLOBAL PUBLIC HEALTH RESEARCHERS TO AVOID JEOPARDISING METHODOLOGICAL AND ETHICAL INTEGRITY OF SCIENTIFIC CONTRIBUTIONS
by Eugene Lee Davids

1. Examine the implications of methodological changes to evidence generation and synthesis for global public health.
2. Reflect on the ethical implications of knowledge generation and evidence syntheses which have poor methodological quality.
3. Consider the ethical implications as researchers, academics and healthcare professionals when generating global public health research.
4. Unpack the ethical dilemmas of duplication, working in silos and draining human resources of global public health research and evidence-based medicine during the pandemic.
5. Critical evaluation of the value that the proposed research has for clinicians who use evidence to inform clinical decision-making which impacts on the health of the public.
6. Does generating knowledge and evidence to inform clinical decision-making where access is controlled or restricted through paid access present challenges in terms of accessibility and the ethical obligation to share knowledge to inform global public health.
7. Examine the risks and benefits of participant engagement in global public health research to inform evidence-based medicine during the COVID-19 pandemic.

of Mandarin and Spanish) and locally (such as isiZulu, isiXhosa and Afrikaans). Researchers should reflect on how the use of only English in the dissemination of knowledge may have limited the overall aim of sharing knowledge.
