Abstract

Total coliforms are a group of bacteria found in high numbers in mammalian intestines; hence their presence in water indicates the possible contamination with faecal material. Total and faecal coliform counts were monitored over a period of 18 months using mFC, m-Endo and CM1046 media together with enzymatic assays on 215 environmental water samples obtained from the Eastern Cape Province of South Africa. A positive correlation, with an R² value of 0.9393 was observed between faecal and total coliform colony units employing mFC and m-Endo media, and 0.8818 using CM1046 media. Also, a positive correlation was observed between Escherichia coli colony-forming units and β-D-galactosidase (B-GAL) activity (R²=0.8542). Overall, this study indicated that faecal contamination of environmental water samples could be monitored by measuring total coliform β-galactosidase activity and total coliform colony-forming units.

Keywords: colony-forming units (CFUs), coliforms, E. coli, β-D-galactosidase (B-GAL), β-D-glucuronidase (GUD)

Introduction

Coliforms are a group of bacteria employed to assess the microbiological quality of water and/or food. Most faecal coliforms are present in large numbers among the intestinal flora of human and other warm-blooded animals, and are thus commonly found in faecal material. As a result, the presence of these non-pathogenic microorganisms in water indicates the potential presence of pathogenic microorganisms of faecal origin (Venter, 2000; Rompré et al., 2002) and consequently a health hazard. It is estimated that 80% of communicable diseases in the world are waterborne (Deví et al., 2008). Analysing for total coliform bacteria and Escherichia coli is the most common method used to test the hygienic quality of drinking water (Huertas et al., 2003; Pitkänen et al., 2007). Bacteria as diverse as Escherichia coli, Citrobacter, Klebsiella, Enterobacter, Serratia, Erwinia and Yersinia are all positive for the traditional coliform test (Standard Methods, 2005). Among the afore-mentioned bacteria, only Escherichia coli appear to be of faecal origin (Goffi et al., 1999; Rompré et al., 2002; Schraft and Watterworth, 2005) (Fig. 1).

However, there have been criticisms on the suitability of total coliforms, as markers of faecal contamination of water and/or food (Goffi et al., 1999; Leclerc et al., 2001; Stevens et al., 2001; Rose and Grimes, 2002; Hörmann and Hänninen, 2006). Studies on total coliforms reveal that they can have an environmental origin besides faecal sources, thus these organisms may not be suitable indicators of faecal contamination (Leclerc et al., 2001). Escherichia coli and enterococci have been shown to be consistently associated with faecal pollution and thus the most reliable indicators of faecal contamination (Leclerc et al., 1999; 2001; Goffi et al., 1999; Rompré et al., 2002; Schraft and Watterworth, 2005). Furthermore, there have been occurrences of total coliforms in the absence of documented waterborne morbidity in the community, and outbreaks where coliforms have not been found (McFeters and Camper, 1983; McFeters et al., 1986). Although the latter could be due to the fact that the currently accepted methods may lead to underestimations of waterborne coliforms (Hudson et al., 1983; McFeters et al., 1986), this does not rule out the unreliability of coliforms as faecal indicators. Despite these setbacks, total coliforms are still being used in national and international guidelines for the microbiological quality assessment of water (Grabow et al., 1999; Noble et al., 2003; Horman et al., 2004; Byamukama et al., 2005).

The presence of total coliforms and E. coli (faecal coliform) could be detected by measuring the activity of β-D-galactosidase (B-GAL) and β-D-glucuronidase (GUD) enzymes respectively (Wutor et al., 2007a). These enzymes hydrolyse a wide range of chromogenic and fluorogenic substrates yielding products which can be monitored spectrophotometrically and fluorometrically.

respectively. In this study, the chromogenic substrates chlorophenol red β-D-galactopyranoside (CPRG), and p-nitrophenyl-β-D-glucuronide (PNPG) were employed to measure B-GAL and GUD activities respectively, while mFc, m-Endo and CM 1046 were used in CFU counts.

In this paper, we examine the relationship between faecal coliform (FC) and total coliform (TC), thus the potential of using TC β-n-galactosidase activity and CFU counts as a measure of faecal coliform contamination of environmental water samples.

**Materials and methods**

Chlorophenol red β-D-galactopyranoside (CPRG), disodium hydrogen phosphate, dihydrogen sodium phosphate were all obtained from Merck (Darmstadt, Germany), p-nitrophenyl-β-D-glucuronide (PNPG) (Merck, Darmstadt, Germany). The media, mFc, m-Endo and CM1046 were obtained from Merck (Darmstadt, Germany), Fisher Scientific (Loughborough, UK) and Oxoid (Hampshire, UK) respectively. The buffers were prepared using water purified with a Milli-Q system (Millipore, Milford, CT, USA). All reagents were of the highest analytical grade available.

**Sampling**

Water collection was performed in accordance with the standard procedures outlined in *Standard Methods*, 2005. Water samples were collected weekly from two points along the Bloukrans River, Grahamstown in the Eastern Cape of South Africa as well as from other sources in the Eastern Cape Province of South Africa for a period spanning 18 months between 2005 and 2006. Samples were collected aseptically in 1 ℓ sterile Pyrex bottles (Schott Duran, Germany), placed on ice and transported immediately to the laboratory and analysed within an hour. Samples were collected in triplicates between 08:00 and 08:30 on each sampling day. In total, 215 samples were studied.

**Enzyme Assays**

The B-GAL assay was performed as described in Wutor et al. (2007b). Briefly, CPRG (80 µg in 20 µℓ water) was mixed with 90 µℓ of environmental (water) sample added to initiate the reaction. The change in absorbance was monitored at 575 nm over 24 h on a PowerWave (Bio-Tek Instruments, USA).

Togo et al. (2006) described the GUD assay employed in the study. PNPG (10 mM) was prepared in 0.1 M Tris-HCl, pH 8.0 containing 0.6 mM CaCl2 buffer. Assay buffer (50 µℓ) and 90 µℓ enzyme solution/water sample were mixed in a 96-well, flat-bottomed micro-titre plate. The reaction was initiated by the addition of 110 µℓ PNPG. Kinetic readings (24 h at 1 h intervals) were performed at 405 nm and 25 °C using a Power Wave spectrophotometer (Bio-Tek Instruments, USA).

In each enzyme assay, 2 sets of controls were set up; an enzyme control and a substrate control. All readings were taken against milli-Q water (Millipore Corporation, USA). All assays were performed in triplicate, unless otherwise stated. All results are reported as means ± standard deviations.

**Microbiological analyses**

Water samples of 100 ml volumes were filtered through membrane filters (Whatman 0.45 µm pore size) and placed on mFc plates for the detection of faecal coliforms at 44.5 °C over 24 h; CM 1046 media (selective E. coli/coliform chromogenic medium) and m-Endo-agar plates (total coliforms) and incubated at 37°C for 24 h, after which colonies were counted. All colonies which developed a pink colour were counted as other coliforms while those that developed a purple colour were counted as *E. coli* on the CM 1046 media (the sum of both pink and purple colony counts gave the total coliform load of the water sample under consideration) while red colonies with metallic reflections were counted as total coliforms (m-Endo agar) and colonies with light to dark blue colonies were counted as faecal coliforms (mFc agar). These were then expressed as coliform colony-forming units (CFU) per 100 ml (Wutor et al., 2007a).

**Results and discussion**

The source of B-GAL enzyme was validated as from *E. coli* by using SDS-PAGE and MALDI-ToF (data not shown). The MALDI-ToF technique has been used successfully in the analysis of proteins, peptides, glycoproteins, oligosaccharides, and oligonucleotides and has the capability of measuring masses to within 0.01% of the molecular mass of the sample (Takah et al., 1997; Whitelegge, 2003; Kammerer et al., 2005). Enzymatic assays were performed alongside growth on selected media to correlate enzymatic activity and colony counts.

Wutor et al. (2007a) in a previous study observed a positive correlation between total coliform CFUs and B-GAL activity; R² of 0.941 for CM 1046 media, and 0.7051 for m-Endo media, while Togo et al. (2006) established a correlation of 0.8909 between GUD activity and *E. coli* CFUs.

**Detection of TC and FC using media**

Generally, we observed a significant (P<0.05) correlation between TC and FC on m-Endo and mFc media with a R² value of 0.9392 and a R² value of 0.8818 for TC and FC on CM 1046 media (Figs. 2 and 3). Though different media were employed in this analysis, the benefits of an early warning signal on the microbiological status of water from assessing only total coliforms cannot be underestimated.

**Detection of TC and FC**

A positive correlation, with an R² value of 0.8542 at 95% confidence interval was observed for *E. coli* colony counts and B-GAL activity (Fig. 4). It must be noted that this value, though lower...
Acknowledgements

In conclusion, one could use total coliform β-galactosidase enzyme activity and CFU determination as a very good measure of microbial water quality assessment. Total coliform measurement may be considered as an imperfect but useful criterion of drinking water quality assessment and should find use at both small and large treatment facilities, as well as in routine analysis.
